AGAWAM SERIES

The Agawam series consists of very deep, well drained soils formed in sandy, water deposited materials. They are level to steep soils on outwash plains and high stream terraces. Slope ranges from 0 to 15 percent. Saturated hydraulic conductivity is moderately high or high in the upper solum and high or very high in the lower solum and substratum. Mean annual temperature is about 48 degrees F. and mean annual precipitation is about 47 inches.

TAXONOMIC CLASS: Coarse-loamy over sandy or sandy-skeletal, mixed, active, mesic Typic Dystrudepts

TYPICAL PEDON: Agawam fine sandy loam in a nearly level cultivated field at an elevation of about 124 feet. (Colors are for moist soil unless otherwise stated.)

Ap--0 to 11 inches; dark grayish brown (10YR 4/2) fine sandy loam; light brownish gray (10YR 6/2) dry; weak medium and coarse subangular blocky structure; very friable; common fine and medium roots; strongly acid; abrupt smooth boundary. (5 to 14 inches thick)

Bw1--11 to 16 inches; dark yellowish brown (10YR 4/4) fine sandy loam; weak medium and coarse subangular blocky structure; very friable; common fine and medium roots; strongly acid; abrupt smooth boundary.

Bw2--16 to 26 inches; light olive brown (2.5Y 5/4) fine sandy loam; weak medium subangular blocky structure; very friable; common fine and medium roots; strongly acid; clear smooth boundary. (Combined thickness of the Bw horizons is 10 to 30 inches)

2C1--26 to 45 inches; olive(5Y 5/3) loamy fine sand; massive; very friable; few fine roots; strongly acid; clear smooth boundary.

2C2--45 to 55 inches; olive brown (2.5Y 4/4) loamy fine sand; massive; very friable; strongly acid; abrupt smooth boundary.

2C3--55 to 65 inches; olive (5Y 5/3) loamy sand; single grain; loose; strongly acid.

TYPE LOCATION: Hampshire County, Massachusetts; Town of Hatfield; 700 feet north of Elm Street at a point 1,600 feet west of its intersection with Prospect Street. USGS Mt. Holyoke quadrangle; Lat. 42 degrees 22 minutes 00 seconds N. and 72 degrees 36 minutes 42 seconds W., NAD 27.

RANGE IN CHARACTERISTICS: Solum thickness ranges from 15 to 35 inches. Coarse fragments range from 0 to 10 percent by volume in the surface, 0 to 30 percent in the B and C horizons above a depth of 40 inches and 0 to 60 percent below. The soil ranges from very strongly acid to slightly acid, unless limed.

The Ap horizon has hue of 7.5YR to 2.5Y, value of 3 or 4, and chroma of 2 to 4. Dry value is 6 or more. It is fine sandy loam, very fine sandy loam, or loam. Undisturbed pedons have an A horizon that has hue of 7.5YR to 2.5Y, value of 2 to 3, and chroma of 1 to 3. It is 1 to 4 inches thick. Some pedons have a thin E horizon directly below the A.

The upper part of the Bw horizon has hue of 5YR to 10YR, value of 4 to 7, and chroma of 3 to 8. The lower part has hue of 10YR to 5Y with value and chroma ranges the same as the upper part. Texture is fine sandy loam, very fine sandy loam, or loam in the upper part and fine sandy loam or very fine sandy loam in the lower part. Structure is very weak, weak or moderate granular or subangular blocky or the horizon is massive.

A BC horizon of sandy loam or loamy sand is present in some pedons. Color and texture ranges are the same as the lower part of the Bw. Structure is very weak, weak or moderate granular or the horizon is massive. It is up to 5 inches thick.

The C horizon has hue of 10YR to 5Y, value of 3 to 7, and chroma of 1 to 4. It is stratified loamy fine sand, loamy sand, fine sand, sand, or their gravelly analogues and is very gravelly below a depth of 40 inches in some pedons. Consistence is very friable or loose.

COMPETING SERIES: These are the Barnstable, Branford, Haven, and Narragansett series. Barnstable soils formed in till over outwash and have rock fragments in the solum that are dominantly angular. Branford soils have hue of 5YR or redder throughout the B and C horizons. Narragansett soils lack stratified layers and have coarse fragments that are dominantly angular. Haven soils typically have more than 40 percent silt in the lower part of the Bw horizon.

GEOGRAPHIC SETTING: Agawam soils are level to steep soils on outwash plains and high stream terraces. Most areas are on slopes that are less than 15 percent. Steeper slopes are on terrace escarpments and steep sides of gullies in dissected outwash plains. The soils formed in sandy water deposited material derived principally from schist, granite, gneiss, and phyllite. Mean annual precipitation ranges from 28 to 55 inches and mean annual air temperature from 45 degrees to 50 degrees F. The mean growing season ranges from 120 to 200 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Enfield, Hadley, Hartland, Hinckley, Merrimac, Ninigret, Occum, Walpole, and Windsor soils on nearby landscapes. The excessively drained Hinckley and Windsor, somewhat excessively drained Merrimac, and well drained Enfield and Hartland soils are on associated outwash terraces and glacial lake plains. Well drained Hadley and Occum soils are on nearby floodplains. The moderately well drained Ninigret and poorly drained Walpole soils are associated in a drainage sequence with Agawam soils.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Well drained. Runoff and internal drainage are negligible to low. Saturated hydraulic conductivity is moderately high or high in the upper solum and high or very high in the lower solum and substratum.

USE AND VEGETATION: Most areas are used for growing cultivated hay, silage corn, tobacco, potatoes, and truck crops. Some areas are used for growing pasture. Native vegetation is forest composed mainly of white pine, gray birch, red maple, red, white, black, and scarlet oaks.

DISTRIBUTION AND EXTENT: Connecticut, Massachusetts, New Hampshire, eastern New York, and Rhode Island; MLRA's 101, 142, 144A, and 145. The series is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Hampden and Hampshire Counties, Massachusetts, 1928.

REMARKS: It should be noted that as a competing series, Haven soils typically have soil temperatures that may be slightly warmer but a precise difference could not be quantified based on available data and historical use.

Diagnostic horizons and other features recognized in this pedon are:

1. Ochric epipedon - the zone from 0 to 11 inches (Ap horizon).
2. Cambic horizon - the zone from 11 to 26 inches (Bw horizons).
3. Contrasting particle-size - the coarse-loamy material contains less than 50 percent fine or coarser sand and the transition zone is less than 12.5 cm thick.

ADDITIONAL DATA: Reference samples from pedons S54MA023006, S58MA011002, S57NH013003, S70CT003001, S85VT027017, S85VT027018, S91MA011008, S93MA011003, S93MA011003, S93MA011004 from numerous counties and states, by NSSL, Lincoln, NE, various years. Pedon S70 CT-3-1 sampled in Hartford, Connecticut. Analysis by Beltsville soil survey laboratory.

BELGRADE SERIES

The Belgrade series consists of very deep, moderately well drained soils formed in glaciolacustrine material. They are nearly level to moderately steep soils on terraces. Slope ranges from 0 to 25 percent. Saturated hydraulic conductivity is moderately high or high in the solum and moderately low to high in the substratum. Mean annual precipitation is about 44 inches, and the mean annual temperature is about 49 degrees F.

TAXONOMIC CLASS: Coarse-silty, mixed, active, mesic Aquic Dystric Eutrudepts

TYPICAL PEDON: Belgrade silt loam - on a 1 percent slope in a cultivated field at an elevation of about 8 meters. (Colors are for moist soil unless otherwise stated.)

Ap--0 to 9 inches; very dark grayish brown (10YR 3/2) very fine sandy loam, light brownish gray (10YR 6/2) dry; very weak fine and medium granular structure; very friable; many fine roots; slightly acid; abrupt smooth boundary. (5 to 10 inches thick)

Bw1--9 to 20 inches; yellowish brown (10YR 5/6) very fine sandy loam; weak fine granular structure; very friable; common fine roots; slightly acid; clear wavy boundary. (6 to 32 inches thick)

BC--20 to 30 inches; light olive brown (2.5Y 5/4) very fine sandy loam; massive; very friable; few very fine roots; common prominent distinct strong brown (7.5YR 5/6) masses of iron accumulation and gray (5Y 5/1) iron depletions; slightly acid; clear wavy boundary. (0 to 12 inches thick)

C1--30 to 42 inches; light olive brown (2.5Y 5/4) very fine sandy loam; massive; very friable; many medium and coarse prominent yellowish red (5YR 4/6) and strong brown (7.5YR 5/6) masses of iron accumulation, and gray (5Y 6/1) iron depletions; slightly acid; abrupt wavy boundary.

C2--42 to 65 inches; gray (5Y 6/1) loamy very fine sand; massive; very friable; common lenses of fine sand; many coarse prominent yellowish red (5YR 4/6) and strong brown (7.5YR 5/6) masses of iron accumulation; neutral.

TYPE LOCATION: Essex County, Massachusetts; Town of Amesbury, 3.2 miles southwest of Amesbury Village, 550 feet north of Pleasant Valley Road and 700 feet east of Amesbury-Merrimac town line. Lat. 42 degrees 49 minutes 30 seconds N., and long. 70 degrees 58 minutes 04 seconds W., NAD 27.

RANGE IN CHARACTERISTICS: Solum thickness ranges from 20 to 44 inches. Reaction ranges from very strongly acid to neutral in the solum and from moderately acid to slightly alkaline in the C horizon; however, some subhorizon between depths of 10 and 30 inches is moderately acid to neutral. Redox depletions with a chroma of 2 or less are within a depth of 24 inches (60 cm). Gravel content ranges from 0 to 5 percent to a depth of 40 inches and 0 to 30 percent below 40 inches.

The Ap horizon has hue of 10YR, value of 3 or 4, and chroma of 2 to 4. Dry value is 6 or more. It is silt loam or very fine sandy loam. Undisturbed areas have an A horizon with colors and textures similar to the Ap.

The Bw horizon has hue of 10YR to 5Y, value of 4 or 5, and chroma of 3 to 6. Some pedons have lower Bw horizons with hue of 10YR to 5Y, value of 4 to 6, and chroma of 2 to 6, with common or many redoximorphic features. The Bw horizon is typically silt loam or very fine sandy loam but includes loamy very fine sand. Structure is weak coarse prismatic, weak fine subangular blocky or weak or moderate, fine or medium granular, or the horizon is massive. Consistence ranges from firm to very friable.

The BC horizon, where present, has characteristics similar to those of the lower Bw horizons.

The C horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 1 to 4. It is silt loam, very fine sandy loam, or loamy very fine sand in the fine-earth fraction. Some pedons have thin strata of loamy fine sand, fine sand, or silt. Below a depth of 40 inches some pedons have unconforming strata of sand or sand and gravel, or very thin strata or varves of contrasting material. The C horizon has common to many redoximorphic features. It is usually massive, but some pedons have platy structure. Consistence ranges from firm to loose.

COMPETING SERIES: There are no other series in this family. The Bridgehampton, Boxford, Dartmouth, Enfield, Georgia, Hartland, Raynham, Scio, Suffield, Tisbury, Unadilla, and Wapping are similar soils in related families. Boxford soils are fine. Georgia soils are coarse-loamy. Suffield soils are coarse-silty over clayey. Bridgehampton, Dartmouth, Enfield, Scio, Tisbury, Unadilla, and Wapping soils have base saturation of less than 60 percent in the upper 30 inches. In addition, Enfield and Tisbury soils have sand and gravel within a depth of 40 inches. Hartland soils do not have redox depletions within a depth of 24 inches. Raynham soils have dominant chroma of 2 or less within a depth of 20 inches.

GEOGRAPHIC SETTING: Belgrade soils are nearly level to moderately steep soils on glaciolacustrine terraces. Slope ranges from 0 to 25 percent. The upper part of the soil formed in water or wind deposited material high in silt and very fine sand. The material below 40 inches is variable and ranges from gravelly sand to silt. Mean annual temperature ranges from 45 to 52 degrees F. and mean annual precipitation ranges from 40 to 47 inches. The frost free season ranges from 135 to 195 days.

GEOGRAPHICALLY ASSOCIATED SOILS: Belgrade soils are in a drainage sequence with the well drained Hartland, poorly drained Raynham, and very poorly drained Birdsall soils. Agawam, Deerfield, Enfield, Haven, Merrimac, Ninigret, Sudbury, Tisbury, and Windsor soils

are on nearby glacial outwash landforms. Hadley, Limerick, Occum, Pootatuck, Rippowam, and Winooski soils are on nearby flood plains.

DRAINAGE AND PERMEABILITY: Moderately well drained. Runoff is negligible to high. Saturated hydraulic conductivity is moderately high or high in the solum and moderately low to high in the substratum.

USE AND VEGETATION: Most areas are cleared and are used mainly for growing grasses, and legumes for hay or pasture, and for silage. Some areas are used for growing potatoes, sweet corn, vegetables, and other crops and some areas are used as urban land. Common trees in woodlots are white, red and black oak, hickory, sugar maple, red maple, ash, tulip, black birch, yellow birch, beech, white pine, and hemlock.

DISTRIBUTION AND EXTENT: Massachusetts, New Hampshire, New York, and Vermont (MLRAs 142, 144A, 144B, 145, and 149B). The soil is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Hartford County, Connecticut, 1959.

REMARKS: Diagnostic horizons and features recognized in this pedon are:

1. Ochric epipedon - the zone from the soil surface to a depth of 9 inches (Ap horizon).
2. Cambic horizon - the zone from 9 to 30 inches (Bw and BC horizon).
3. Coarse-silty feature - the zone from 10 to 40 inches contains less than 15 percent sand that is coarser than very fine sand, including gravel, and about 5 to 10 percent clay (Bw, BC and Cl horizons).

National Cooperative Soil Survey
U.S.A.

Established Series

CANTON SERIES

The Canton series consists of very deep, well drained soils formed in a loamy mantle underlain by sandy till. They are on nearly level to very steep moraines, hills, and ridges. Slope ranges from 0 to 45 percent. Saturated hydraulic conductivity is moderately high or high in the solum and high or very high in the substratum. The mean annual temperature is about 9 degrees C and the annual precipitation is about 1205 mm.

TAXONOMIC CLASS: Coarse-loamy over sandy or sandy-skeletal, mixed, superactive, mesic Typic Dystrudepts

TYPICAL PEDON: Canton fine sandy loam on a west-facing, convex, 8 percent slope in an extremely stony forested area at an elevation of about 210 meters. (Colors are for moist soil unless otherwise noted.)

Oi-- 0 to 5 cm; slightly decomposed plant material; (0 to 13 cm thick.)

A-- 5 to 13 cm; very dark grayish brown (10YR 3/2) fine sandy loam; weak fine granular structure; friable; common fine roots; 5 percent gravel; very strongly acid (pH 4.6); abrupt smooth boundary. (3 to 10 cm thick.)

Bw1-- 13 to 30 cm; yellowish brown (10YR 5/6) fine sandy loam; weak medium subangular blocky structure; friable; common fine and medium roots; 5 percent gravel; very strongly acid (pH 4.6); clear smooth boundary.

Bw2-- 30 to 41 cm; yellowish brown (10YR 5/4) fine sandy loam; weak medium subangular blocky structure; friable; common fine and medium roots; 5 percent gravel; strongly acid (pH 5.1); clear smooth boundary.

Bw3-- 41 to 56 cm; yellowish brown (10YR 5/4) gravelly fine sandy loam; weak medium subangular blocky; friable; common fine and medium roots; 15 percent gravel; strongly acid (pH 5.1); abrupt smooth boundary. (Combined thickness of the Bw horizons is 43 to 84 cm.)

2C-- 56 to 170 cm; grayish brown (2.5Y 5/2) gravelly loamy sand; massive; friable; 25 percent gravel; moderately acid (pH 5.6).

TYPE LOCATION: Worcester County, Massachusetts; Town of Douglas; 150 feet south on Wallum Lake Road from the junction of Cedar and South West Main Streets, and 165 feet

southwest of Wallum Lake Road. USGS Oxford, MA quadrangle; Latitude 42 degrees, 2 minutes, 43.2 seconds N., and Longitude 71 degrees, 45 minutes, 44.8 seconds W., NAD 83.

RANGE IN CHARACTERISTICS: Solum thickness is commonly 46 to 91 cm, but ranges to 36 cm. It corresponds closely to the depth to the sandy till. Rock fragment content consists of 0 to 20 percent gravel and 0 to 5 percent cobbles in the solum. Stones and boulders are 0 to 15 percent of the surface and solum. Gravel content is 10 to 30 percent, cobbles 5 to 10 percent, and stones 0 to 10 percent in the substratum. Rock fragments are dominantly granite, gneiss, and quartzite. The soil ranges from extremely acid to moderately acid.

The O horizons, where present, consist of slightly, moderately, and/or highly decomposed organic material.

The A horizon has hue of 7.5YR or 10YR, value of 2 to 4, and chroma of 1 to 3. Texture is sandy loam, fine sandy loam, loam, or very fine sandy loam in the fine-earth fraction. Some pedons have an Ap horizon with properties similar to the A horizon. It is up to 20 cm thick.

Some pedons have a thin E or AE horizon that has hue of 7.5YR or 10YR, value of 3 to 5 and chroma of 1 or 2 with similar textures to the A horizon. It is up to 8cm thick.

The upper Bw horizons commonly have hue of 10YR, and includes 7.5YR when a high ratio of ammonium oxalate extractable iron to dithionite-citrate extractable iron (greater than 0.15) exists, value of 4 or 5, and chroma of 4 to 8. The lower Bw horizons have hue of 10YR or 2.5Y, value of 4 to 7, and chroma of 4 to 8. Texture of the fine-earth fraction of the Bw horizons is commonly fine sandy loam and less commonly sandy loam, loam, and very fine sandy loam. Structure of the Bw horizons is granular or subangular blocky.

Some pedons have a Bs, Bh, or BC horizon with texture similar to the Bw horizons.

The 2C horizon typically has hue of 2.5Y or 5Y, value of 5 to 7, and chroma of 2 or 3. In some pedons hue is 10YR with chroma of 4 to 6. The texture of the fine-earth fraction is loamy fine sand or coarser. It is single grain or massive. Consistence is friable, very friable or loose. Thin lenses or small pockets of firm or very firm finer textured material are common below 91 cm.

COMPETING SERIES: There are no other soils currently in the same family.

The Agawam, Barnstable, Branford, Brookfield, Charlton, Haven, and Narragansett series are in closely related families. The Agawam, Branford, and Haven soils have stratified sand or sand and gravel in the series control section. In addition, the Branford soils have hues redder than 7.5YR throughout the B horizon. Barnstable soils formed in till over outwash and have less than 30 percent fine sand in the lower part of the Bw horizon. Brookfield soils formed in sulfur bearing parent materials and have a ratio of ammonium oxalate extractable iron to dithionite-citrate extractable iron less than 0.15 and have pedogenic iron contents greater than 1 percent throughout the pedon. Charlton soils lack a lithologic discontinuity of abrupt change in sand distribution. Narragansett soils have more than 55 percent silt and very fine sand in the solum.

GEOGRAPHIC SETTING: Canton soils are on moraines and glaciated upland hills and ridges. Slope ranges from 0 to 45 percent. The soils formed in an acid coarse loamy supraglacial melt out till over loose sandy till of Wisconsin age derived from gneiss, granite and schist along with some fine-grained sandstone in some pedons. The loamy mantle in some pedons is influenced or derived from eolian sources. The climate is humid temperate. The mean annual air temperature is 7 to 11 degrees C, and the mean annual precipitation ranges from 1016 to 1295 mm.

GEOGRAPHICALLY ASSOCIATED SOILS: The Newfields series is the moderately well drained member of the same toposequence. The Agawam, Haven, Merrimac, and Warwick soils are on nearby glacial outwash kames and plains. The Barnstable, Brookfield, Charlton, Cheshire, Dutchess, Gloucester, Hollis, Montauk, Narragansett, and Paxton soils are on nearby glaciated uplands. Brookfield, Charlton, Cheshire, Dutchess, Gloucester, Hollis, Montauk, and Paxton soils do not have a contrasting particle size in the control section.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Well drained. Runoff is negligible to medium. Internal drainage is medium. Saturated hydraulic conductivity is moderately high or high in the solum and high or very high in the substratum.

USE AND VEGETATION: Mostly forested. Some areas have been cleared of surface stones and are used for crops and pasture. Native vegetation is forest composed of eastern white pine, northern red, white, and black oaks, hickory, red maple, sugar maple, gray birch, yellow birch, beech, eastern hemlock, and white ash.

DISTRIBUTION AND EXTENT: Glaciated uplands in Connecticut, Massachusetts, New Hampshire, eastern New York, and Rhode Island, also in the Massachusetts Coastal Islands; MLRAs 144A, 145, and 149B. The series is of large extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Herkimer County, New York, 1969.

REMARKS:

Diagnostic horizons and features recognized in this pedon are:
1) Ochric epipedon - the zone from 0 to 13 cm (Oi and A horizons).
2) Cambic horizon - the zone from 13 to 56 cm (Bw1, Bw2, and Bw3 horizons).
3) Contrasting particle size - the coarse-loamy material contains less than 50 percent fine sand or coarser, and the transition zone between the two parts of the particle-size control section is less than 12 cm thick. (Coarse-loamy over sandy or sandy skeletal).
4) Lithologic discontinuity - abrupt change in sand distribution at 56 cm (2C horizon).
6) Particle-size control section - the zone from 30 to 105 cm (Bw1, Bw2, Bw3, and 2C horizons).

CHARLTON SERIES

The Charlton series consists of very deep, well drained soils formed in loamy melt-out till. They are nearly level to very steep soils on moraines, hills, and ridges. Slope ranges from 0 to 60 percent. Saturated hydraulic conductivity is moderately high or high. Mean annual temperature is about 9 degrees C and mean annual precipitation is about 1205 mm.

TAXONOMIC CLASS: Coarse-loamy, mixed, superactive, mesic Typic Dystrudepts

TYPICAL PEDON: Charlton fine sandy loam - forested, very stony, at an elevation of about 170 meters. (Colors are for moist soil unless otherwise noted.)

Oe -- 0 to 4 cm; black (10YR 2/1) moderately decomposed forest plant material. (0 to 5 cm thick.)

A -- 4 to 10 cm; dark brown (10YR 3/3) fine sandy loam; weak fine granular structure; very friable; many fine roots; 5 percent gravel; very strongly acid; abrupt smooth boundary. (2 to 15 cm thick.)

Bw1 -- 10 to 18 cm; brown (7.5YR 4/4) fine sandy loam; weak coarse granular structure; very friable; many fine and medium roots; 5 percent gravel; very strongly acid; clear wavy boundary.

Bw2 -- 18 to 48 cm; yellowish brown (10YR 5/6) fine sandy loam; weak medium subangular blocky structure; very friable; common fine and medium roots; 10 percent gravel and cobbles; very strongly acid; clear wavy boundary.

Bw3 -- 48 to 69 cm; light olive brown (2.5Y 5/4) gravelly fine sandy loam; massive; very friable; few medium roots; 15 percent gravel and cobbles; very strongly acid; abrupt wavy boundary. (Combined thickness of the Bw horizons is 35 to 91 cm.)

C -- 69 to 165 cm; grayish brown (2.5Y 5/2) gravelly fine sandy loam with thin lenses of loamy sand; massive; friable, some lenses firm; few medium roots; 25 percent gravel and cobbles; strongly acid.

TYPE LOCATION: New Haven County, Connecticut; town of Middlebury, 3800 feet along Long Meadow Road from the intersection with South Street, 450 feet southeast along a gravel road and 50 feet west of the gravel road, 400 feet northeast of Long Meadow Pond, in a wooded area. USGS Naugatuck topographic quadrangle, Latitude 41 degrees 29 minutes 48.40 seconds

N., Longitude 73 degrees 7 minutes 04.59 seconds W., NAD 1983.

RANGE IN CHARACTERISTICS: Thickness of the solum ranges from 31 to 109 cm. Depth to bedrock is commonly more than 180 cm. Rock fragments range from 5 to 35 percent by volume to a depth of 100 cm and up to 50 percent below 100 cm. Except where the surface layer is stony, the fragments are mostly subrounded gravel and typically make up 60 percent or more of the total rock fragments. Unless limed, reaction ranges from extremely acid to moderately acid.

The O horizon, where present, ranges from slightly decomposed to highly decomposed plant material.

The A horizon has hue of 7.5YR or 10YR, value of 2 or 3, and chroma of 1 to 3. Disturbed pedons have an Ap horizon with value of 3 or 4 and chroma of 2 to 4. The A or Ap horizon is sandy loam, fine sandy loam, or loam in the fine-earth fraction. It has weak or moderate granular structure and is friable or very friable.

Some pedons have a thin AE or E horizon below the O horizon or a thin E horizon below the A horizon. It has hue of 10YR or 2.5Y, value of 4 to 6, and chroma of 1 to 3. Texture, structure, and consistence are like the A horizon.

The upper part of the Bw horizon has commonly hue of 7.5YR or 10YR, and includes 7.5YR when a high ratio of ammonium oxalate extractable iron to dithionite-citrate extractable iron (greater than 0.15) exists, and value and chroma of 4 to 6. The lower part of the Bw horizon has hue of 10YR or 2.5Y and value and chroma of 4 to 6. Texture of the Bw horizon is loam, fine sandy loam, or sandy loam with less than 65 percent silt plus very fine sand in the fine earth fraction. It has weak granular or subangular blocky structure. Consistence is friable or very friable.

Some pedons have a BC horizon with value and chroma like the lower part of the Bw horizon, but includes hue of 5Y. The BC horizon commonly has texture, structure, and consistence like the Bw horizon but the range includes geologically derived structure appearing in the form of thin plates.

The C horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 2 to 6. Texture is loam, fine sandy loam, or sandy loam in the fine-earth fraction, with pockets or thin lenses of loamy sand. The horizon is massive or has plates of geogenic origin. Consistence commonly is very friable or friable but in some pedons includes firm.

COMPETING SERIES: These are Chadakoin, Chatfield, Maplecrest, Riverhead, Stinger and Valois. Chadakoin and Valois soils formed in till derived primary from sedimentary rock parent materials. Chatfield soils have a lithic contact at 50 to 100 cm below the mineral soil surface. Maplecrest soils formed in till derived from red sedimentary rock parent materials. Riverhead soils formed in glacial outwash deposits and have sandy textures in the substratum. Stinger soils are moderately deep to a paralithic contact and formed in colluvium on mountain side slopes in Oregon.

GEOGRAPHIC SETTING: Charlton soils are nearly level to very steep soils on moraines and glaciated upland hills and ridges. Slope ranges from 0 to 60 percent. The soils formed in acid melt-out till derived mainly from schist, gneiss, or granite. Mean annual temperature ranges from 7 to 11 degrees C and mean annual precipitation commonly ranges from 940 to 1245 cm, but the range includes as low as 660 cm in some places east of the Adirondack Mountains in the Champlain Valley of New York. The growing season ranges from 115 to 185 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Acton, Brookfield, Chatfield, Essex, Hollis, Leicester, Rainbow, Ridgebury, Sutton, Wapping, Whitman, and Woodbridge soils on nearby landscapes. The moderately well drained Sutton and the poorly drained Leicester soils are associated in a drainage sequence. Acton and Wapping soils are moderately well drained. Brookfield soils formed in iron sulfide bearing parent materials and have a ratio of ammonium oxalate extractable iron to dithionite-citrate extractable iron less than 0.15 and have pedogenic iron contents greater than 1 percent throughout the pedon. Chatfield soils have bedrock within a depth of 50 to 100 cm. Essex soils have a sandy particle-size control section and a dense substratum. Hollis soils have bedrock within a depth of 25 to 50 cm. Rainbow and Woodbridge soils are moderately well drained with a dense substratum. Ridgebury soils are poorly drained and have a dense substratum. Whitman soils are very poorly drained with a dense substratum.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Well drained. Runoff is negligible to medium. Saturated hydraulic conductivity is moderately high or high in the mineral soil.

USE AND VEGETATION: Areas cleared of stones are used for cultivated crops, specialty crops, hay, and pasture. Many scattered areas are used for community development. Stony areas are mostly wooded. Common trees are northern red, white, and black oak, hickory, sugar maple, red maple, black and gray birch, white ash, beech, white pine, and hemlock.

DISTRIBUTION AND EXTENT: Glaciated uplands in Connecticut, Massachusetts, New Hampshire, New York, and Rhode Island. MLRAs 142,144A, and 145. The series is of large extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts

SERIES ESTABLISHED: Worcester County, Massachusetts, 1922.

REMARKS: Diagnostic horizons and features recognized in this pedon include:
1. Ochric epipedon - the zone from 0 to 10 cm (Oe and A horizons).
2. Cambic horizon - the zone from 10 to 69 cm (Bw1, Bw2, and Bw3 horizons).
3. Particle-size class - coarse-loamy in the control section from 29 to 109 cm.

CHATFIELD SERIES

The Chatfield series consists of well drained soils formed in loamy melt-out till. They are moderately deep to bedrock. They are nearly level to very steep soils on bedrock-controlled hills and ridges. Slope ranges from 0 to 70 percent. Crystalline bedrock is at depths of 50 to 100 cm. Saturated hydraulic conductivity is moderately high or high in the mineral soil. Mean annual temperature is about 9 degrees C, and mean annual precipitation is about 1205 mm.

TAXONOMIC CLASS: Coarse-loamy, mixed, superactive, mesic Typic Dystrudepts

TYPICAL PEDON: Chatfield fine sandy loam, on a 13 percent slope in a wooded area. (Colors are for moist soil unless otherwise noted).

Oi -- 0 to 3 cm, slightly decomposed leaf, needle, and twig litter; extremely acid, pH 4.2. (0 to 15 cm thick.)

A -- 3 to 5 cm, very dark gray (10YR 3/1) fine sandy loam, gray (10YR 5/1), dry; weak fine subangular blocky structure; friable; many fine and medium roots throughout; 5 percent mixed gravel and cobbles; very strongly acid, pH 4.5; abrupt smooth boundary. (1 to 25 cm thick.)

Bw1-- 5 to 33 cm, strong brown (7.5YR 5/6) gravelly fine sandy loam; weak fine subangular blocky structure; friable; common fine roots throughout and common medium roots throughout; 15 percent mixed gravel and cobbles; very strongly acid, pH 4.5; abrupt wavy boundary.

Bw2 -- 33 to 76 cm, strong brown (7.5YR 5/6) gravelly fine sandy loam; moderate medium subangular blocky structure; friable; few fine roots throughout; 20 percent mixed rock fragments; very strongly acid, pH 4.5; abrupt irregular boundary. (Combined thickness of the Bw horizons is 10 to 80 cm.)

2R -- 76 cm; fractured slightly-weathered schist bedrock.

TYPE LOCATION: Merrimack County, New Hampshire; Town of Epsom, 450 feet north-northwest from point 3,550 feet southwest along Old Mountain Road from intersection of Mountain Road and Tarlton Road. USGS Gossville, NH topographic quadrangle; Latitude 43 degrees, 11 minutes, 55.79 seconds N. and Longitude 71 degrees, 19 minutes, 22.31 seconds W., WGS 1984.

RANGE IN CHARACTERISTICS: Solum thickness ranges from 40 to 97 cm. Depth to

bedrock ranges from 50 to 100 cm from the mineral soil surface. Rock fragments range from 5 to 50 percent by volume in the A horizon and from 5 to 35 percent in the B and C horizons. Rock fragments are typically gravel or channers, but include cobbles, stones, boulders and flagstones, particularly just above the bedrock.

The O horizon has hue of 5YR to 2.5Y, value of 2 or 3, and chroma of 0 to 2. It is slightly, intermediately, and/or highly decomposed plant material. Reaction ranges from extremely acid to moderately acid.

The A, or Ap horizon where present, has hue of 7.5YR to 2.5Y, value of 2 to 4, and chroma of 1 to 4. Dry value is 6 or higher. Texture is sandy loam, fine sandy loam, very fine sandy loam, loam, or silt loam in the fine-earth fraction. Structure is granular. Consistence is friable or very friable. Reaction ranges from extremely acid to moderately acid, unless limed.

The AB or BA horizon, where present, has hue of 7.5YR to 2.5Y, value of 3 or 4, and chroma of 2 to 4. Texture is similar to the A horizon.

The Bw horizon commonly has hue of 10YR or 2.5Y, and includes 7.5YR when a high ratio of ammonium oxalate extractable iron to dithionite-citrate extractable iron (greater than 0.15) exists, value of 3 to 6, and chroma of 4 to 6. Texture is similar to the A horizon. The Bw horizon has subangular blocky or granular structure and is friable or very friable. Reaction ranges from very strongly acid to moderately acid.

Some pedons have a BC horizon with color and texture similar to the C horizon.

The C horizon, where present, has hue of 7.5YR to 5Y, value of 4 or 5, and chroma of 2 to 4, and the 7.5YR hue is limited to horizons having a high ratio of ammonium oxalate extractable iron to dithionite-citrate extractable iron (> 0.15). Texture is sandy loam, fine sandy loam, very fine sandy loam, loam, or silt loam in the fine-earth fraction and may have lenses or pockets of loamy sand. It is massive and may have plate-like divisions. It is friable or firm. Reaction ranges from very strongly through moderately acid.

The 2R horizon is dominantly schist, granite, or gneiss bedrock. In places it is massive, but it dominantly has vertical and horizontal fractures in the upper 30 to 76 cm.

COMPETING SERIES: These are the Chadakoin, Charlton, Maplecrest, Riverhead, Stinger, and Valois series. Chadakoin, Maplecrest, and Valois soils formed in till derived primary from sedimentary rock parent materials and are greater than 100 cm to bedrock. Charlton soils formed in similar parent material to that of Chatfield but are greater than 150 cm to bedrock. Riverhead soils formed in glacial outwash deposits and are greater than 100 cm to bedrock. Stinger soils are not from Region R and have a paralithic contact.

GEOGRAPHIC SETTING: Chatfield soils are nearly level through very steep, and are on bedrock-controlled glaciated upland landscapes. The soils formed in a moderately thick mantle of melt-out till overlying granite, gneiss, or schist bedrock. Slope ranges from 0 to 70 percent. Mean annual precipitation ranges from 660 to 1270 mm, mean annual temperature ranges from 7

to 13 degrees C, and the frost free season ranges from 130 to 180 days. Elevation ranges from 0 to 305 meters above sea level.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Brimfield, Brookfield, Cardigan, Charlton, Hollis, Narragansett, Nipmuck, and Paxton soils and their wetter associates on nearby landscapes where the soil mantle is deeper than 100 cm. Brimfield, Brookfield and Nipmuck soils formed in sulfur bearing parent materials and have a ratio of ammonium oxalate extractable iron to dithionite-citrate extractable iron less than 0.15 and have pedogenic iron contents greater than 1 percent throughout the pedon. Brookfield, Charlton, Narragansett, and Paxton soils are very deep soils. Cardigan soils are moderately deep soils that formed in till derived from phyllite, slate, shale, and schist. Hollis soils are shallow to bedrock and are on nearby ridge crests and areas adjacent to rock outcrops.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Well drained. Potential for surface runoff ranges from low to high. Saturated hydraulic conductivity is moderately high or high in the mineral soil.

USE AND VEGETATION: Most areas of Chatfield soils are in woodland. Major tree species include white and northern red oaks, sugar maple, beech, eastern hemlock, eastern white pine, eastern red cedar, and shagbark hickory. Some small cleared areas are used for pasture, are idle, or are sites for residential and recreational development.

DISTRIBUTION AND EXTENT: Connecticut, eastern New York, Massachusetts, New Jersey, and New Hampshire. MLRAs 142, 143, 144A and 145. The soils are of large extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts

SERIES ESTABLISHED: Orange County, New York, 1940.

REMARKS: Diagnostic horizons and features recognized in this pedon are:
Ochric epipedon - the zone from 0 to 5 cm (Oi and A horizons).
Cambic horizon - the zone from 5 to 76 cm (Bw1 and Bw2 horizons).
Lithic contact - bedrock at 76 cm (2R horizon).
Particle-size control section - the zone from 28 to 76 cm (part of the Bw1 horizon and all of the Bw2 horizon).
Lithologic discontinuity - at a depth of 76 cm.

ADDITIONAL DATA: M.S. Thesis work by Shawn McVey, University of Connecticut, 2006. Full characterization data for pedons with User Pedon IDs of S1955NH015003, S1982CT007005, S1982CT007005, S1982NY061001, S1995NH013003, S1995NJ037003, S1998NY005001, S1999NY005004, S2000NY005002, S2000NY005004, S2000NY005008, S2000NY119002, S2000NY119003, S2002CT005007, and S2002CT005008. Pedons analyzed by the NSSL, Lincoln, NE. LOCATION DEERFIELD MA+CT NH NY RI VT

Established Series
Rev. CAW-MFF
01/2017

DEERFIELD SERIES

The Deerfield series consists of very deep, moderately well drained soils formed in glaciofluvial deposits. They are nearly level to strongly sloping soils on terraces, deltas, and outwash plains. Slope ranges from 0 to 15 percent. Saturated hydraulic conductivity is high or very high. Mean annual temperature is about 49 degrees F. and mean annual precipitation is about 47 inches.

TAXONOMIC CLASS: Mixed, mesic Aquic Udipsamments

TYPICAL PEDON: Deerfield loamy sand in a cultivated field at an elevation of about 114 meters. (Colors are for moist soil.)

Ap --0 to 9 inches; very dark grayish brown (10YR 3/2) loamy sand, light brownish gray (10YR 6/2) dry; weak fine granular structure; very friable; many fine roots; moderately acid; abrupt smooth boundary. (6 to 12 inches thick)

Bw1 --9 to 15 inches; yellowish brown (10YR 5/6) loamy sand; very weak fine granular structure; very friable; common fine roots; moderately acid; clear wavy boundary.

Bw2 --15 to 19 inches; yellowish brown (10YR 5/4) loamy sand; very weak fine and medium granular structure; very friable; common fine roots; common medium prominent strong brown (7.5YR 5/8) masses of iron accumulation; moderately acid; clear smooth boundary. (Combined thickness of the Bw horizons is 5 to 27 inches thick)

BC --19 to 27 inches; olive brown (2.5Y 4/4) sand; single grain; loose; few fine roots; common fine and medium prominent strong brown (7.5YR 5/8) and reddish brown (5YR 4/4) masses of iron accumulation, and common fine and medium distinct grayish brown (10YR 5/2) iron depletions; moderately acid; abrupt smooth boundary. (0 to 20 inches thick)

C --27 to 65 inches; olive gray (5Y 4/2) sand grading with depth to dark gray (5Y 4/1) fine sand; single grain; loose; common fine and medium prominent strong brown (7.5YR 5/8) and reddish brown (5YR 4/4) masses of iron accumulation, and common fine and medium distinct grayish brown (10YR 5/2) iron depletions; moderately acid.

TYPE LOCATION: Franklin County, Massachusetts; Town of Montague, 800 feet west of a point on West Mineral Road that is 4,000 feet from the intersection of West Mineral Road and Millers Falls Road, in a cultivated field. Lat. 42 degrees 35 minutes 36.4 seconds N. and long. 72 degrees 30 minutes 48.2 seconds W., NAD 83.

RANGE IN CHARACTERISTICS: Solum thickness ranges from 15 to 40 inches. Gravel, generally fine pebbles, ranges from 0 to 15 percent in the solum and 0 to 20 percent in the substratum. Reaction ranges from very strongly acid through slightly acid unless limed. Iron depletions with chroma of two or less are between depths of 15 and 40 inches from the mineral soil surface.

The Ap horizon has hue of 10YR, value of 2 to 4, and chroma of 1 to 3. It is fine sandy loam, sandy loam, loamy fine sand, loamy sand, fine sand, or sand. Undisturbed pedons commonly have an O horizon, and a thin sequence of A, E, and Bs, Bhs or Bh horizons, or an AB horizon. The Ap or A horizon has weak or moderate very fine to medium granular structure.

The Bw horizon has hue of 7.5YR to 2.5Y, value of 4 to 6, and chroma of 3 to 6. Texture of the upper part of the Bw horizon, within a depth of 10 inches from the soil surface, has the same range as the A horizon. Below 10 inches texture is loamy fine sand, loamy sand, fine sand, sand or coarse sand. Structure is weak, very fine to medium granular or subangular blocky, or is single grain.

The BC horizon, where present, has hue of 7.5YR to 2.5Y, value of 3 to 6, and chroma of 2 to 4. Texture range is the same as the lower part of the Bw horizon. Structure is weak, very fine to medium granular, or is single grain.

The C horizon has hue of 7.5YR to 5Y, value of 4 to 6, and chroma of 1 to 4. Texture is loamy fine sand, loamy sand, fine sand, sand or coarse sand. It is commonly single grain but may be very weak or weak granular.

COMPETING SERIES: These are the Algansee, Altmar, Brems, Brockatonorton, Elnora, Fortress, Livonia, Morocco, Ottokee, Partridge, Tedrow, and Zaborowsky series. The Algansee, Brems, Brockatonorton, Meckling, Morocco, Ottokee, Partridge, Tedrow, and Zaborowsky soils are from outside of region R. Algansee soils have an irregular decrease of organic matter with depth. Altmar soils have rock fragments dominated by sandstone. Birchwood soils formed in sandy sediments over glacial till. Brems and Ottokee soils have sola more than 40 inches thick, and Ottokee soils have lamellae. Elnora soils contain more fine sand in the lower part of the series control section. Fortress soils formed in anthropotransported soil material from eolian sand, outwash, ordredging activities. Livonia soils formed in glaciolacustrine parent material with neutral to moderately alkaline reaction and average less than 960 mm of annual precipitation. Meckling soils are calcareous throughout. Morocco soils have redox features within a depth of 15 inches. Partridge soils have bedrock at depths of 20 to 40 inches. Tedrow and Zaborosky soils have carbonates.

GEOGRAPHIC SETTING: Deerfield soils are level to strongly sloping soils on terraces, deltas, and outwash plains. Slope gradients are commonly 0 to 3 percent, but range to 15 percent. The soils formed in thick deposits of sand derived mainly from granite, gneiss and quartzite, but in places containing materials from schist and sandstone. The sand is poorly graded; medium sand is generally dominant and typically contains little or no gravel. Mean annual temperature ranges from 45 to 52 degrees F. and the mean annual precipitation typically ranges from 38 to 55

inches but the range includes as low as 26 inches in some places east of Adirondack Mountains in the Champlain Valley of New York. The mean growing season ranges from 120 to 200 days.

GEOGRAPHICALLY ASSOCIATED SOILS: Deerfield soils are in a drainage sequence that includes the excessively drained Carver and Windsor soils, the somewhat poorly drained Pipestone and Wareham soils, and the very poorly drained Scarboro soils. The well drained Agawam, somewhat excessively drained Merrimac, and the excessively drained Hinckley and Penwood soils are on nearby glacial outwash landforms and have sandy and gravelly substrata. The excessively drained Plymouth, somewhat excessively drained Gloucester, well drained Canton, Charlton, Cheshire, Essex and Paxton, and moderately well drained Woodbridge soils are on nearby glacial till uplands.

DRAINAGE AND PERMEABILITY: Moderately well drained. Runoff is negligible to low. Saturated hydraulic conductivity is high or very high.

USE AND VEGETATION: Mainly cleared and used for truck crops, tobacco, potatoes, hay, pasture and silage corn. Forested areas have pitch pine, white pine, gray birch, red maple, oaks, and sugar maple. Some areas are in urban uses.

DISTRIBUTION AND EXTENT: New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut and New York. (MLRA's 101, 142, 144A, 144B, 145, and 149B) The soils of this series are moderately extensive.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Franklin County, Massachusetts, 1964.

REMARKS: The use of very weak structure in the A horizon is no longer an approved choice for grade of structure and has been removed from this description. Some pedons may exist where this grade of structure has been described.

Diagnostic horizons and features recognized in this pedon include:
1. Ochric epipedon - the zone from 0 to 9 inches (Ap horizon).
2. Aquic feature - the zone from 19 to 40 inches has redox depletions with chroma of 2 or less. (BC and C horizons).

LOCATION HINCKLEY MA+CT ME NH NJ NY RI VT

Established Series
Rev. CAW-SMF-DCP
08/2017

HINCKLEY SERIES

The Hinckley series consists of very deep, excessively drained soils formed in glaciofluvial materials. They are nearly level through very steep soils on outwash terraces, outwash plains, outwash deltas, kames, kame terraces, and eskers. Saturated hydraulic conductivity is high or very high. Slope ranges from 0 to 60 percent. Mean annual temperature is about 7 degrees C, and mean annual precipitation is about 1143 mm.

TAXONOMIC CLASS: Sandy-skeletal, mixed, mesic Typic Udorthents

TYPICAL PEDON: Hinckley loamy sand in woodland at an elevation of about 240 meters. (All colors are for moist soil.)

Oe -- 0 to 3 cm; moderately decomposed plant material derived from red pine needles and twigs. (0 to 5 cm thick.)

Ap -- 3 to 20 cm; very dark grayish brown (10YR 3/2) loamy sand; weak fine and medium granular structure; very friable; many fine and medium roots; 5 percent fine gravel; very strongly acid; abrupt smooth boundary. (3 to 25 cm thick.)

Bw1 -- 20 to 28 cm; strong brown (7.5YR 5/6) gravelly loamy sand; weak fine and medium granular structure; very friable; common fine and medium roots; 20 percent gravel; very strongly acid; clear smooth boundary.

Bw2 -- 28 to 41 cm; yellowish brown (10YR 5/4) gravelly loamy sand; weak fine and medium granular structure; very friable; common fine and medium roots; 25 percent gravel; very strongly acid; clear irregular boundary. (Combined thickness of the Bw horizon is 8 to 41 cm.)

BC -- 41 to 48 cm; yellowish brown (10YR 5/4) very gravelly sand; single grain; loose; common fine and medium roots; 40 percent gravel; strongly acid; clear smooth boundary. (0 to 13 cm thick)

C -- 48 to 165 cm; light olive brown (2.5Y 5/4) extremely gravelly sand consisting of stratified sand, gravel and cobbles; single grain; loose; common fine and medium roots in the upper 20 cm and very few below; 60 percent gravel and cobbles; moderately acid.

TYPE LOCATION: Worcester County, Massachusetts; Town of Petersham, Harvard Forest, 240 feet north of Tom Swamp Road at a point 1.15 miles east of the intersection of Athol Road

and Tom Swamp Road. USGS Athol, MA topographic quadrangle, Latitude 42 degrees, 30 minutes, 41.8 seconds N., and Longitude 72 degrees, 12 minutes, 28.9 seconds W., NAD 1983.

RANGE IN CHARACTERISTICS: Solum thickness ranges from 30 to 87 cm. Rock fragment content of the solum ranges from 5 through 50 percent gravel, 0 through 30 percent cobbles, and 0 through 3 percent stones. Rock fragment content of individual horizons of the substratum ranges from 10 through 55 percent gravel, 5 through 25 percent cobbles, and 0 through 5 percent stones. In some places gravel content throughout the soil ranges up through 75 percent. The soil ranges from extremely acid through moderately acid, except where limed.

The O horizons, where present, consist of slightly, moderately, and/or highly decomposed plant material. They have hue N or 2.5YR through 7.5YR, value of 2 or 3, and chroma of 0 through 3.

The Ap horizon has hue of 7.5YR or 10YR, value of 2 through 4, and chroma of 1 through 4. Texture of the fine-earth fraction is very fine sandy loam, fine sandy loam, sandy loam, coarse sandy loam, loamy fine sand, loamy sand, or loamy coarse sand. Structure is weak or moderate very fine through coarse granular or subangular blocky. Consistence is friable or very friable. Undisturbed areas have an A horizon that has hue of 10YR, value of 2 or 3, and chroma of 1 through 4.

Some pedons have thin E, Bhs, Bh, or Bs horizons below the A horizon.

The upper part of the Bw horizon has hue of 7.5YR or 10YR, value of 3 through 5, and chroma of 3 through 8. The lower part has hue of 7.5YR through 2.5Y, value of 3 through 6, and chroma of 3 through 8. Texture, to a depth of 25 cm from the surface, is fine sandy loam, sandy loam, coarse sandy loam, loamy fine sand, loamy sand, or loamy coarse sand in the fine-earth fraction. Below 25 cm it is loamy fine sand, loamy sand, loamy coarse sand, fine sand, sand, or coarse sand in the fine-earth fraction. Structure commonly is weak fine and/or medium granular or the horizon is structureless, but ranges through weak subangular blocky in some places. It is very friable, friable, or loose.

Some pedons have a BC horizon with characteristics similar to both the B and 2C horizons.

The C horizon has hue of 7.5YR through 5Y, value of 3 through 7, and chroma of 2 through 8. Texture is loamy fine sand, loamy sand, loamy coarse sand, fine sand, sand or coarse sand in the fine-earth fraction, and is stratified.

COMPETING SERIES: These are the Bonaparte, Manchester, Mecosta, Multorpor, Otisville, Quonset, and Rikers series. Mecosta and Multorpor soils are from outside Land Resource Region R. Bonaparte soils have carbonates within a depth of 100 cm. Manchester soils have 5YR or redder hue in the Bw and C horizons. Mecosta soils are calcareous and Multorpor soils do not have Bw horizons. Otisville soils have rock fragments dominated by sandstone, shale, and slate. Quonset soils have rock fragments dominated by phyllite, slate, and shale. Rikers soils have carboliths in the soil.

GEOGRAPHIC SETTING: Hinckley soils are nearly level through very steep soils on outwash

terraces, outwash plains, outwash deltas, kames, kame terraces, and eskers. Slope is generally 0 through 8 percent on tops of the terraces, outwash plains and deltas. Slope of 8 through 60 percent or more are on the kames, eskers and margins of the outwash plains, deltas, and terraces. The soils formed in glaciofluvial sand and gravel derived principally from granite, gneiss, and schist. Mean annual temperature ranges from 7 to 13 degrees C, and mean annual precipitation ranges from 1016 to 1270 mm. Length of the growing season ranges from 140 through 240 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Agawam, Canton, Charlton, Deerfield, Essex, Gloucester, Horseneck, Mashpee, Massasoit, Merrimac, Paxton, Pompton, Riverhead, Scarboro, Sudbury, Walpole, Wareham, and Windsor soils on nearby landscapes. Horseneck, Pompton, and Riverhead soils are commonly associates in the extreme southern portions of MLRA 144A. Agawam, Merrimac, and Riverhead soils are similar to Hinckley soils, but have cambic horizons. Canton, Charlton, Essex, Gloucester, and Paxton soils formed in till. Deerfield, Horseneck, and Sudbury soils are moderately well drained and Horseneck and Sudbury soils have Cambic horizons. Pompton soils have Cambic horizons and are moderately well and somewhat poorly drained. Scarboro soils are very poorly drained. Windsor soils have less than 15 percent rock fragments. Mashpee and Massasoit soils are poorly drained with spodic horizons. Walpole and Wareham soils are poorly drained.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Excessively drained. Surface runoff is negligible through low. Saturated hydraulic conductivity is high or very high.

USE AND VEGETATION: Cleared areas are used for hay, pasture, and silage corn. In the southern Connecticut River Valley, Hinckley soils are used for growing tobacco and truck crops and in eastern Massachusetts, truck crops. Most areas are forested, brush land or used as urban land. Northern red, black, white, scarlet and scrub oak, eastern white and pitch pine, eastern hemlock, and gray birch are the common trees. Unimproved pasture and idle land support hardhack, little bluestem, bracken fern, sweet fern, and low bush blueberry.

DISTRIBUTION AND EXTENT: Connecticut, southern Maine, Massachusetts, New Hampshire, northern New Jersey, New York, Rhode Island, and Vermont. MLRA's 101, 141, 142, 144A, 145, and 149B. The series is extensive.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Oneida County, New York, 1913.

REMARKS: The use of the Hinckley series in frigid areas of Maine, and in MLRA 143 and 144B, is relict to before temperature classes. These have been removed from the SC file.

Diagnostic horizons and features recognized in this pedon are:
1. Ochric epipedon - the zone from 3 to 20 cm (Ap horizon).
2. Sandy-skeletal feature - the zone from 25 to 100 cm has a weighted average content of rock fragments of 51 percent and a particle size of the fine-earth fraction is sandy (Bw, BC, and C horizons).

ADDITIONAL DATA: Reference samples from pedons S55NH015002, S56MA011002, S56MA011003, S57MA023005, S58NH015002, S73MA009001, S73MA005002, S73MA009004, S73MA005005, S96NH013003 from Massachusetts and New Hampshire, samples by NSSL, Lincoln, NE, various dates.

LOCATION LIMERICK CT MA NH NY VT
Established Series
Rev. MHS-SHG-DCP
03/2010

LIMERICK SERIES

The Limerick series consists of very deep, poorly drained soils on flood plains. They formed in loamy alluvium. Saturated hydraulic conductivity is moderately high or high. Slope ranges from 0 through 3 percent. Mean annual precipitation is about 44 inches (1118 millimeters) and mean annual temperature is about 45 degrees F. (7 degrees C).

TAXONOMIC CLASS: Coarse-silty, mixed, superactive, nonacid, mesic Fluvaquentic Endoaquepts

TYPICAL PEDON: Limerick silt loam, on a nearly level slope in hay land at an elevation of about 10 feet. (Colors are for moist soil unless otherwise noted.)

Ap-- 0 to 8 inches (0 to 20 centimeters); dark grayish brown (10YR 4/2) silt loam, light brownish gray (10YR 6/2) dry; moderate medium granular structure; friable; common very fine and fine and few medium roots; moderately acid; clear smooth boundary. (3 to 10 inches, 8 to 25 centimeters thick.)

BCg1-- 8 to 20 inches (20 to 50 centimeters); olive gray (5Y 4/2) silt loam; massive; friable; few very fine and fine roots; common medium prominent dark yellowish brown (10YR 4/4) and yellowish brown (10YR 5/4 and 10YR 5/6) soft masses of iron accumulation; moderately acid; clear smooth boundary.

BCg2-- 20 to 36 inches (50 to 91 centimeters); olive gray (5Y 4/2) silt loam; massive; common medium prominent dark yellowish brown (10YR 4/4) and yellowish brown (10YR 5/4 and 10YR 5/6) soft masses of iron accumulation; moderately acid; clear smooth boundary.

BCg3-- 36 to 54 inches; (91 to 137 centimeters) dark gray (5Y 4/1) silt loam; massive; common medium prominent dark yellowish brown (10YR 4/4) and yellowish brown (10YR 5/4 and 10YR 5/6) soft masses of iron accumulation; moderately acid; clear smooth boundary. (Combined thickness of the BCg horizons ranges from 6 to more than 60 inches (15 to 152 centimeters.)

Cg-- 54 to 65 inches (137 to 165 centimeters); dark greenish gray (5GY 4/1) silt loam; massive; few, fine prominent dark yellowish brown (10YR 4/4) and yellowish brown (10YR 5/4 and 10YR 5/6) soft masses of iron accumulation; neutral.

TYPE LOCATION: Hartford County, Connecticut; town of Wethersfield, 1200 feet east on Second Lane Road from Interstate 91 underpass, 50 feet south of Second Lane Road, on the Hartford South. USGS Hartford South topographic quadrangle, Latitude 41 degrees, 41 minutes,

52 seconds N., Longitude 72 degrees, 38 minutes, 22 seconds W., NAD 1983, on the floodplain of the Connecticut River.

RANGE IN CHARACTERISTICS: Thickness of the solum ranges from 17 through more than 60 inches (43 through 152 centimeters). Depth to bedrock is more than 60 inches (152 centimeters). Reaction ranges from strongly acid through neutral. The weighted average of fine and coarser sands, in the particle-size control section, is less than 15 percent.

The A or Ap horizon has hue of 10YR through 5Y, value of 3 or 4, and chroma of 1 or 2. Texture is commonly silt loam but includes very fine sandy loam. Structure is typically weak or moderate, fine or medium granular. Some A horizons have weak or moderate medium subangular blocky structure. Consistence is friable or very friable. Redoximorphic features, where present, are few through many, fine through coarse and faint through prominent.

Some pedons have one or more Ab horizons with hue of 10YR through 5Y, value of 3 or 4 and chroma of 1 or 2. Texture is commonly silt loam but includes very fine sandy loam. The horizons are massive and friable.

Some pedons have a Bg horizon, 6 through 8 inches (15 through 20 centimeters) thick, with hue of 10YR through 5Y, value of 4 through 6, and chroma of 1 or 2. Texture is commonly silt loam, but includes silt and very fine sandy loam. Structure is weak granular or subangular blocky, or the horizon is massive. Consistence is friable. Redoximorphic features are few through many, fine through coarse and distinct or prominent.

The BCg horizon, where present, has hue of 10YR through 5Y, value of 4 through 6 and chroma of 1 or 2. Texture is commonly silt loam, but includes silt and very fine sandy loam. Strata of loamy very fine sand, very fine sand, or fine sand .2 through .5 inches (.5 through 1.3 centimeters) thick are present in some horizons. The horizon is massive and friable or very friable. Redoximorphic features range from few through many, fine through coarse and faint through prominent.

The Cg horizon, where present, has hue of 10YR through 5GY, or is neutral, value of 4, and chroma of 0 through 2. Texture is commonly silt loam but includes silt and very fine sandy loam. Some pedons have thin strata (less than .2 inches) (.5 centimeters) that vary in color, texture, or reaction. Redoximorphic features, where present, are few through many and fine or medium prominent. The horizon is massive and friable.

Some pedons have a 2Cg horizon below a depth of 40 inches (100 centimeters). It has hue of 10YR through 5Y, value of 3 through 5, and chroma of 1 through 4. Texture is fine sandy loam through sand.

COMPETING SERIES: Oridia and Skokomish soils are currently the only other series in this family. Oridia and Skokomish series are from Land Reasource Region A in the Pacific Northwest.

The Lim, Rippowam, and Rumney series are in related families. They have a weighted average of fine sand or coarser in the particle-size control section of more than 15 percent. Rumney soils have a cooler mean annual soil temperature.

GEOGRAPHIC SETTING: Limerick soils are on the flood plains of major rivers and their larger tributaries. In some places they are on the flood plains of small streams. They may be on broad flat areas or in shallow depressions. The soils formed in recent alluvial deposits that are dominantly silt and very fine sand. Mean annual temperature ranges from about 45 through 52 degrees F. (7 through 11 degrees C.), and mean annual precipitation ranges from 30 through 50 inches (762 through 1270 millimeters). The frost-free season ranges from 105 through 180 days.

GEOGRAPHICALLY ASSOCIATED SOILS: Limerick soils are the poorly drained member of the drainage sequence that includes the well drained Hadley, the moderately well drained Winooski, and the very poorly drained Saco soils. Common associated soils on nearby terraces are the Agawam, Enfield, Hinckley, Merrimac, and Windsor series.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Poorly drained. Saturated hydraulic conductivity is moderately high or high. Most areas are flooded for periods of several days each year, usually in late winter or early spring.

USE AND VEGETATION: Most areas are used for long term hay and pasture. A few areas have been drained, and cultivated crops are grown. Common trees in wooded areas are red maple and eastern white pine. Additional woody species are alders, willows, black ash, green ash, swamp birch, river birch, silky willow, and pussy willow. Common herbaceous species include cinnamon fern, nettle, and skunk cabbage.

DISTRIBUTION AND EXTENT: Connecticut, Massachusetts, New Hampshire, New York, and Vermont; MLRAs 142, 144A, and 145. The series is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Aroostook County, Maine, 1943.

REMARKS: 1. With this revision the classification is changed from Coarse-silty, mixed, active, nonacid, mesic Fluvaquentic Endoaquepts to Coarse-silty, mixed, superactive, nonacid, mesic Fluvaquentic Endoaquepts. This reflects a review of current lab data available for this series, S70MA015004, S70MA015005 and S06CT003-001 were some of the selected lab pedons used to make the determination.

2. The use of the Limerick series in Maine, and in MLRA 143 and 144B, is relict to before temperature classes. These have been removed from the SC file.

3. Diagnostic horizons and features recognized in this pedon include:

a. Ochric epipedon - the zone from 0 to 8 inches (0 to 20 centimeters) (Ap horizon).
b. Cambic horizon - the zone from 8 to 54 inches (20 to 137 centimeters) (BCg horizons).
c. Aquept feature - Within 20 inches (50 centimeters) of the soil surface the matrix has chroma of 2 or less with redox concentrations.
d. Fluvaquentic feature: The organic-carbon content is presumed to decrease irregularly with depth between 10 through 50 inches (25 through 125 centimeters).
e. Nonacid reaction class - the pH is presumed to be 5.0 or more in 0.01m $CaCl_2$ in at least some part of the control section.
f. The material composing the Cg layer is presumed to change color upon exposure to air thereby not meeting the criteria for a Cambic horizon.

MERRIMAC SERIES

The Merrimac series consists of very deep, somewhat excessively drained soils formed in outwash. They are nearly level through very steep soils on outwash terraces and plains and other glaciofluvial landforms. Slope ranges from 0 through 35 percent. Saturated hydraulic conductivity is high or very high. Mean annual temperature is about 48 degrees F. (9 degrees C.) and mean annual precipitation is about 42 inches (1067 millimeters).

TAXONOMIC CLASS: Sandy, mixed, mesic Typic Dystrudepts

TYPICAL PEDON: Merrimac fine sandy loam cultivated, at an elevation of about 122 meters. (Colors are for moist soil.)

Ap -- 0 to 10 inches (0 to 25 centimeters); very dark grayish brown (10YR 3/2) fine sandy loam, light brownish gray (10YR 6/2) dry; weak fine and medium granular structure; very friable; many fine roots; 10 percent fine gravel; strongly acid; abrupt smooth boundary. (1 to 14 inches (3 to 36 centimeters) thick.)

Bwl -- 10 to 15 inches (25 to 38 centimeters); brown (7.5YR 4/4) fine sandy loam; weak fine and medium granular structure; very friable; common fine roots; 10 percent fine gravel; strongly acid; clear wavy boundary.

Bw2 -- 15 to 22 inches (38 to 56 centimeters); dark yellowish brown (10YR 4/4) gravelly sandy loam; weak fine and medium granular structure; very friable; few fine roots; 15 percent gravel; strongly acid; clear wavy boundary.

Bw3 -- 22 to 26 inches (56 to 66 centimeters); dark yellowish brown (10YR 4/4) gravelly loamy sand; very weak fine granular structure; very friable; few fine roots; 25 percent gravel; moderately acid; clear wavy boundary. (Combined thickness of the Bw horizons is 6 to 34 inches (15 to 86 centimeters).)

2C -- 26 to 65 inches (66 to 165 centimeters); 80 percent yellowish brown (10YR 5/4) and 20 percent dark grayish brown (10YR 4/2) very gravelly sand; single grain; loose; stratified; few fine roots in upper 4 inches; 40 percent gravel, 10 percent cobbles; moderately acid.

TYPE LOCATION: Franklin County, Massachusetts; Town of Leverett, 2.75 miles south-southeast of Montague Village, 0.13 miles southeast of Cranberry Pond, just west of Route 63. USGS Williamsburg, MA topographic quadrangle, Latitude 42 degrees, 29 minutes, 51 seconds

N. and Longitude 72 degrees, 31 minutes, 12 seconds W., NAD 1983.

RANGE IN CHARACTERISTICS: Solum thickness ranges from 18 through 36 inches (46 through 91 centimeters). Rock fragments are commonly granite or gneiss or schist but up to 25 percent are flat, fine-grained slate, shale, or phyllite fragments. The upper part of the solum commonly has 2 through 20 percent gravel, but includes cobbles in some pedons, and the lower part 5 through 30 percent. The substratum contains 2 through 55 percent gravel and 5 through 15 percent cobbles. Total volume of rock fragments in the particle-size control section is less than 35 percent. Clay content is less than 18 percent. Reaction ranges from extremely acid through moderately acid, unless limed.

The O horizon, where present, ranges in thickness from 2 through 5 inches (4 through 13 centimeters). They have hue 2.5YR through 10YR, value 2 or 3, and chroma 1 through 3. They are fibric, hemic, or sapric material.

The Ap, A, or AE horizon has hue of 7.5YR or 10YR, value of 2 through 4, and chroma of 1 through 4. Texture is fine sandy loam, sandy loam, or very fine sandy loam in the fine-earth fraction.

The E horizon, where present, ranges in thickness from 1 through 3 inches (3 through 8 centimeters). They have hue 5YR through 10YR, value 4 through 6, and chroma 1 through 4. Texture is sandy loam or coarse sandy loam in the fine-earth fraction. Some pedons have thin Spodic horizons less than 2 inches (5 centimeters) thick with hue 7.5YR or 10YR, value 4, and chroma 3 through 6.

The Bw horizon has hue of 7.5YR or 10YR in the upper part and 7.5YR through 2.5Y in the lower part. Value ranges from 3 through 6 and chroma from 3 through 8. Texture of the upper part of the Bw horizon is fine sandy loam, sandy loam, coarse sandy loam, or very fine sandy loam in the fine-earth fraction. It has granular or subangular blocky structure or the horizon is massive. The lower part of the B horizon is sandy loam, coarse sandy loam, loamy coarse sand, loamy fine sand, or loamy sand in the fine-earth fraction. Sandy loam textures do not extend below a depth of 27 inches (69 centimeters), but a minimum thickness of 5 inches (13 centimeters) of sandy loam overlies any lower B or 2C horizon that is loamy fine sand or coarser. The B subhorizon that lies above the 2C horizon in many pedons is single grain. Some pedons have a BC horizon that is similar to the lower part of the Bw.

The 2C horizon has hue of 10YR through 5Y and ranges widely in value and chroma. It consists of stratified coarse sand, sand, gravel, and cobbles and has a weighted texture of gravelly or very gravelly sand or coarse sand. Some pedons have thin lenses of loamy fine sand or fine sand.

COMPETING SERIES: These are the Hartford and Knickerbocker series. Hartford soils have hues of 5YR or redder in the Bw horizon. Knickerbocker soils generally have less rock fragments in the substratum and the fragments are commonly slate and dark shale.

GEOGRAPHIC SETTING: Merrimac soils are level to very steep soils on outwash plains and valley trains, and associated kames, eskers, stream terraces and water deposited parts of

moraines. The steeper slopes are on the margin escarpments of terraces and plains, and on eskers and kames. Slope ranges from 0 through 35 percent. The soils formed in water sorted gravelly and sandy material derived mainly from granitic, gneissic, and some schistose rocks. Mean annual precipitation ranges from 28 through 55 inches (711 through 1397 millimeters); mean annual air temperature ranges from 45 through 50 degrees F. (7 through 10 degrees C.), mean growing season ranges from 120 through 200 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Agawam, Hinckley, Mashpee (T), Massasoit (T), Sudbury, Scarboro, Walpole, and Windsor soils on nearby landscapes. The well drained Agawam soils are coarse-loamy over sandy or sandy-skeletal. The excessively drained Hinckley soils are sandy-skeletal. The very poorly drained Scarboro soils are in depressions. The moderately drained Sudbury soils are on adjacent, slightly lower landforms. The poorly drained Mashpee (T), Massasoit (T), and Walpole soils are in drainageways and on low landforms. The excessively drained Windsor soils have loamy fine sand to sand textures in the Bw horizon and lack rock fragments.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Somewhat excessively drained. Runoff is negligible through medium. Saturated hydraulic conductivity is high or very high.

USE AND VEGETATION: Most areas are cultivated and used for growing hay, pasture, silage, corn, or truck crops. Some areas are used to grow tobacco in the Connecticut River Valley in Massachusetts and Connecticut. Some areas are forested with mostly white pine, gray birch, hemlock, red maple, and red, black, white, and scarlet oaks.

DISTRIBUTION AND EXTENT: Massachusetts, Connecticut, New Hampshire, New York, Vermont, and Rhode Island. MLRA's 142, 144A, 145, and 149B. The series is extensive.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Merrimack County, New Hampshire, 1906.

REMARKS: The use of the Merrimac series in Maine, and in MLRA 143 and 144B, is relict to before temperature classes. These have been removed from the SC file.

Diagnostic horizons and other features recognized in this pedon are:

1. Ochric epipedon - the zone from 0 to 10 inches (0 to 25 centimeters) (Ap horizon).
2. Cambic horizon - the zone from 10 to 22 inches (25 to 56 centimeters) (Bw horizon).

LOCATION OCCUM CT +MA NH NY VT
Established Series
Rev. MFF-SMF
07/2006

OCCUM SERIES

The Occum series consists of very deep, well drained loamy soils formed in alluvial sediments. They are nearly level soils on flood plains, subject to common flooding. Slope ranges from 0 to 3 percent. Saturated hydraulic conductivity is moderately high or high in the loamy layers and high or very high in the sandy substratum. Mean annual temperature is about 50 degrees F., and mean annual precipitation is about 43 inches.

TAXONOMIC CLASS: Coarse-loamy, mixed, superactive, mesic Fluventic Dystrudepts

TYPICAL PEDON: Occum fine sandy loam in a hayfield at an elevation of about 200 feet. (Colors are for moist soil unless otherwise noted.)

Ap--0 to 10 inches; dark brown (10YR 3/3) fine sandy loam, pale brown (10YR 6/3) dry; weak fine and medium granular structure; very friable; many very fine and fine roots; moderately acid; clear smooth boundary. (5 to 12 inches thick)

Bw1--10 to 17 inches; dark yellowish brown (10YR 4/4) fine sandy loam; weak medium subangular blocky structure; very friable; common very fine and fine roots; moderately acid; clear smooth boundary.

Bw2--17 to 28 inches; dark yellowish brown (10YR 4/6) sandy loam; weak medium subangular blocky structure; very friable; few very fine and fine roots; moderately acid; clear smooth boundary. (Combined thickness of the Bw horizons is 14 to 35 inches.)

C1--28 to 32 inches; yellowish brown (10YR 5/4) loamy sand; single grain; loose; moderately acid; clear smooth boundary.

C2--32 to 42 inches; brown (10YR 5/3) and light olive brown (2.5Y 5/4) sand; single grain; loose; 10 percent gravel; moderately acid; clear smooth boundary.

C3--42 to 65 inches; brown (10YR 5/3) and light olive brown (2.5Y 5/4) very gravelly coarse sand; single grain; loose; 35 percent gravel; moderately acid.

TYPE LOCATION: Hartford County, Connecticut; town of Granby, 50 feet north of Mechanicsville Road at a point 2,300 feet west of Route 10 and 50 feet east of East Branch Salmon Brook. USGS Tariffville topographic quadrangle, latitude 41 degrees 58 minutes 15 seconds N., longitude 72 degrees 48 minutes 11 seconds W., NAD 27.

RANGE IN CHARACTERISTICS: Thickness of the solum and depth to the coarse-textured substratum range from 20 to 40 inches. Gravel ranges from 0 to 15 percent by volume in the solum and from 0 to 60 percent in the substratum. Some pedons have up to 10 percent cobbles in the substratum. Unless limed, reaction ranges from very strongly acid to slightly acid.

The A or Ap horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 1 to 4. Texture is very fine sandy loam, fine sandy loam, or sandy loam. It has weak or moderate granular structure and is friable or very friable.

The Bw horizon has hue of 7.5YR to 2.5Y, value of 3 to 8, and chroma of 3 to 6. It is commonly fine sandy loam or sandy loam, but the range includes very fine sandy loam or loam in the upper part. Some pedons have thin strata of loam, very fine sandy loam, or silt loam. The Bw horizon has granular or subangular blocky structure, or it is massive. Consistence is friable or very friable. Some pedons have thin Ab horizons.

The C horizon has hue of 7.5YR to 5Y, value of 3 to 7, and chroma of 2 to 6. Some pedons have redoximorphic features below a depth of 4 feet. Texture of individual layers ranges from loamy fine sand to coarse sand in the fine-earth fraction. Included in some pedons are thin loamy and/or extremely gravelly strata. Also, some pedons have a loamy C horizon layer just below the Bw horizon. The C horizon is single grain and loose in the sandy part. The loamy part is typically massive and friable. The thickness and number of subhorizons is variable and corresponds to the thickness and variability of
the alluvial deposits.

COMPETING SERIES: McNulty and Wenonah are other soils currently in the same family. McNulty soils are from outside of LRR R. McNulty soils average more than 60 inches of precipitation per year. Wenonah soils formed in alluvium containing sandstone, siltstone, and shale.

GEOGRAPHIC SETTING: Occum soils are nearly level soils on flood plains, along rivers and streams. Slope ranges from 0 to 3 percent. The soils formed in recent alluvium derived mostly from gneiss, granite, and schist. Mean annual temperature ranges from 45 to 54 degrees F., mean annual precipitation ranges from 35 to 50 inches but the range includes as low as 26 inches in some places east of Adirondack Mountains in the Champlain Valley of New York. The growing season ranges from 115 to 190 days.

GEOGRAPHICALLY ASSOCIATED SOILS: The Agawam, Enfield, Hadley, Haven, Hinckley, Lim, Limerick, Merrimac, Pootatuck, Rippowam, Saco, Suncook, Windsor, and Winooski series are on nearby landscapes. The moderately well drained Pootatuck and the poorly drained Rippowam soils are associated in a drainage sequence. Agawam, Enfield, Haven, and Merrimac soils have a regular decrease in organic carbon with depth. Hadley and Hamlin soils are coarse-silty. Pootatuck soils have low chroma mottles within a 24 inch depth. Hinckley and Windsor soils are on nearby terraces and outwash plains. Lim, Limerick, Saco, and Winooski soils are wetter silty floodplain associates. Suncook soils are sandy, excessively drained soils on floodplains.

DRAINAGE AND PERMEABILITY: Well drained. Surface runoff is negligible to low. Saturated hydraulic conductivity is moderately high or high in the loamy layers and high or very high in the sandy substratum. Many areas of these soils flood for short periods each year, but typically not during the growing season. The soils on higher positions flood occasionally.

USE AND VEGETATION: Cleared areas are used for cultivated crops, hay, and pasture. Common trees in wooded areas are sycamore, white pine, white, yellow, and gray birch, red maple, sugar maple, hemlock, and red and white oak.

DISTRIBUTION AND EXTENT: Holocene floodplains in Connecticut, Massachusetts, New Hampshire, New York, and Vermont; MLRAs 142, 144A and 145. The series is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts

SERIES ESTABLISHED: Windham County, Connecticut, 1980.

REMARKS: Cation exchange activity class placement determined from a review of limited lab data and similar or associated soils.

Diagnostic horizons and features recognized in this pedon are:

1. Ochric epipedon - the zone from 0 to 10 inches (Ap horizon).
2. Cambic horizon - the zone from 10 to 28 inches (Bw1, Bw2 horizons).
3. Fluventic feature - irregular decrease in organic carbon with depth and organic carbon is greater than 0.2 percent within 1.25 meters.
4. Particle-size class - averages coarse-loamy in the particle size control section from 10 to 40 inches (Bw1, Bw2, C1, C2 horizons).

LOCATION PIPESTONE MI+CT IN MA NH NY

Established Series
Rev. JDL-NWS-MLK
09/2012

PIPESTONE SERIES

The Pipestone series consists of very deep, somewhat poorly drained soils formed in sandy outwash on outwash plains, lake plains, beach ridges, and water-worked till plains. Slope ranges from 0 to 8 percent. Mean annual precipitation is about 889 mm (35 inches), and mean annual temperature is about 10.0 degrees C (50 degrees F).

TAXONOMIC CLASS: Sandy, mixed, mesic Typic Endoaquods

TYPICAL PEDON: Pipestone sand, on an east-facing, convex, 1 percent slope in an idle field. (Colors are for moist soil unless otherwise stated.)

Ap--0 to 20 cm (8 inches); very dark brown (10YR 2/2) sand, dark grayish brown (10YR 4/2) dry; moderate medium granular structure; very friable; many fine roots; slightly acid; abrupt smooth boundary. [0 to 25 cm (10 inches) thick]

E--20 to 28 cm (8 to 11 inches); grayish brown (10YR 5/2) sand; moderate medium granular structure; very friable; common fine roots; common medium distinct dark yellowish brown (10YR 3/4) masses of oxidized iron in the matrix; moderately acid; abrupt broken boundary. [0 to 25 cm (10 inches) thick]

Bhs--28 to 38 cm (11 to 15 inches); dark reddish brown (5YR 3/3) sand; weak medium subangular blocky structure; very friable; few fine roots; common fine distinct brown (7.5YR 4/4) masses of oxidized iron in the matrix; strongly acid; abrupt wavy boundary. [0 to 25 cm (10 inches) thick]

Bs--38 to 79 cm (15 to 31 inches); yellowish brown (10YR 5/6) sand; single grain; loose; moderately acid; abrupt wavy boundary. [10 to 58 cm (4 to 23 inches) thick]

C--79 to 152 cm (31 to 60 inches); light brownish gray (10YR 6/2) sand; single grain; loose; slightly acid.

TYPE LOCATION: Berrien County, Michigan; about 4 miles northeast of Benton Harbor; 1,172 feet south and 99 feet west of the northeast corner of sec. 28, T. 3 S., R. 18 W.; USGS Benton Heights topographic quadrangle; lat. 42 degrees 10 minutes 59.5 seconds N. and long. 86 degrees 23 minutes 54 seconds W., WGS 84.

RANGE IN CHARACTERISTICS:

Thickness of the solum: 51 to 127 cm (20 to 50 inches)
Rock fragment content: 0 to 10 percent gravel throughout

Ap horizon:
Hue: 7.5YR or 10YR
Value: 2 to 4
Chroma: 1 to 3
Texture: sand, fine sand, loamy sand, loamy fine sand, or loamy coarse sand
Reaction: extremely acid to neutral

A horizon, where present:
Hue: 7.5YR or 10YR, or is neutral
Value: 2 to 4
Chroma: 0 to 3
Texture: sand, fine sand, loamy sand, loamy fine sand, or loamy coarse sand
Reaction: extremely acid to neutral

Some forested pedons have partially or well decomposed O horizons of forest litter up to 13 cm (5 inches) thick.

E horizon:
Hue: 7.5YR or 10YR
Value: 5 to 7
Chroma: 1 to 3
Texture: sand, loamy sand, fine sand, loamy fine sand, coarse sand, or loamy coarse sand
Reaction: extremely acid to neutral

Bhs horizon:
Hue: 5YR to 10YR
Value: 2 or 3
Chroma: 2 or 3
Texture: sand, loamy sand, fine sand, coarse sand, or loamy coarse sand
Ortstein content: 0 to 30 percent of the surface area exposed in a vertical cut through the Bhs horizon and is present in less than 50 percent of the pedons
Reaction: extremely acid to moderately acid

Bs horizon in pedons without a Bhs horizon:
Hue: 5YR or 7.5YR
Value: 3 or 4
Chroma: 4
Texture: sand, loamy sand, loamy fine sand, fine sand, coarse sand, or loamy coarse sand
Reaction: extremely acid to moderately acid

Bs horizon in pedons with a Bhs horizon:
Hue: 5YR to 10YR
Value: 3 to 6

Chroma: 4 to 8
Iron and manganese concretions: present in some pedons
Texture: sand, loamy sand, loamy fine sand, fine sand, coarse sand, or loamy coarse sand
Reaction: extremely acid to moderately acid

BC horizon, where present:
Hue: 10YR
Value: 5 to 7
Chroma: 4 to 6
Texture: sand, loamy sand, loamy fine sand, fine sand, coarse sand, or loamy coarse sand
Reaction: very strongly acid to neutral

C horizon:
Hue: 7.5YR or 10YR
Value: 5 to 7
Chroma: 2 to 6
Texture: sand, fine sand, coarse sand, or loamy coarse sand
Reaction: very strongly acid to neutral

COMPETING SERIES: There are no other series in the same family.

GEOGRAPHIC SETTING: Pipestone soils are on outwash plains, lake plains, beach ridges, and till plains of Wisconsinan age. Slope ranges from 0 to 8 percent but are dominantly 0 to 4 percent. Pipestone soils formed in sandy outwash. Mean annual precipitation ranges from 711 to 914 mm (28 to 36 inches). Mean annual temperature ranges from 7.2 to 10.0 degrees C (45 to 50 degrees F).

GEOGRAPHICALLY ASSOCIATED SOILS: The excessively drained Oakville and Grattan soils and the poorly drained or very poorly drained Granby, Kingsville, and Newton soils are in a drainage sequences with Pipestone soils.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Somewhat poorly drained. The water table fluctuates from near the surface during prolonged wet periods to depths greater than 122 cm (4 feet) in dry seasons. Depth to the top of a seasonal high water table ranges from 15 to 46 cm (0.5 to 1.5 feet) between October and June in normal years. Potential for surface runoff is negligible or very low. Saturated hydraulic conductivity is high or very high. Permeability is rapid.

USE AND VEGETATION: A large part is or has been cultivated. Some areas are in permanent pasture. Special crops such as blueberries, cucumbers, and melons are important crops on this soil. Many areas are in various stages of reforestation. Natural forests are American basswood, eastern cottonwood, northern red oak, bitternut hickory, white ash, swamp white oak, and red maple.

DISTRIBUTION AND EXTENT: MLRAs 96, 97, 98, 99, 142, 144A, 149B in southern Michigan, northeastern Indiana, Connecticut, Massachusetts, New Hampshire and New York.

The series is of large extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: AMHERST, MASSACHUSETTS

SERIES ESTABLISHED: Gratiot County, Michigan, 1975.

REMARKS: Diagnostic horizons and features recognized in this pedon are:
Ochric epipedon: from the surface to a depth of 28 cm (11 inches) (Ap and E horizons).
Albic horizon: from a depth of 20 to 28 cm (8 to 11 inches) (E horizon).
Spodic horizon: from a depth of 28 to 38 cm (11 to 15 inches) (Bhs horizon).

LOCATION POOTATUCK CT+MA NH NY RI VT

Established Series
Rev. MFF-SMF-GS
01/2013

POOTATUCK SERIES

The Pootatuck series consists of very deep, moderately well drained loamy soils formed in alluvial sediments. They are nearly level soils on floodplains subject to frequent to occasional flooding. Slope ranges from 0 to 3 percent. Saturated hydraulic conductivity is moderately high or high in the loamy upper layers and high or very high in the sandy substratum. Mean annual temperature is about 10 degrees Celsius, and mean annual precipitation is about 1190 millimeters.

TAXONOMIC CLASS: Coarse-loamy, mixed, active, mesic Fluvaquentic Dystrudepts

TYPICAL PEDON: Pootatuck fine sandy loam - cutover woodland. (Colors are for moist soil.)

A-- 0 to 10 centimeters; very dark grayish brown (10YR 3/2) fine sandy loam; weak medium granular structure; friable; common fine and medium roots; strongly acid; clear wavy boundary. (7 to 23 centimeters thick)

Bw1-- 10 to 41 centimeters; dark yellowish brown (10YR 4/4) fine sandy loam; weak medium subangular blocky structure; friable; common fine and medium roots; strongly acid; clear wavy boundary.

Bw2-- 41 to 53 centimeters; brown (10YR 4/3) fine sandy loam; weak medium subangular blocky structure; friable; common fine and medium roots; moderately acid; few medium prominent strong brown (7.5YR 5/6) masses of iron concentration and few medium faint grayish brown (10YR 5/2) iron depletions; gradual wavy boundary.

Bw3-- 53 to 74 centimeters; dark brown (10YR 3/3) sandy loam; weak medium subangular blocky structure; friable; common medium faint grayish brown (10YR 5/2) iron depletions and common medium prominent strong brown (7.5YR 5/6) masses of iron accumulation; common fine roots; moderately acid; clear wavy boundary. (Combined thickness of the Bw horizons is 36 to 94 centimeters.)

C1-- 74 to 89 centimeters; brown (10YR 4/3) sand; single grain; loose; few fine roots; common medium faint grayish brown (10YR 5/2) iron depletions and common medium prominent strong brown (7.5YR 5/6) masses of iron concentration; moderately acid; clear wavy boundary.

C2-- 89 to 100 centimeters; grayish brown (2.5Y 5/2) sand; single grain; loose; 5 percent gravel; few fine faint pale brown (10YR 6/3) masses of iron concentrations; moderately acid; clear wavy

boundary.

C3-- 100 to 165 centimeters; grayish brown (10YR 5/2) gravelly sand; single grain; loose; 25 percent gravel; moderately acid.

TYPE LOCATION: Fairfield County, Connecticut; town of Easton, 800 feet northwest along Connecticut Route 58 from the intersection with Silver Hill Road, 200 feet east Route 58, and 80 feet west of the Aspetuck River; USGS Botsford topographic quadrangle, latitude 41 degrees 16 minutes 40 seconds N., longitude 73 degrees 19 minutes 32 seconds W, NAD 27.

RANGE IN CHARACTERISTICS: Thickness of the solum and depth to the coarse-textured substratum range from 50 to 100 centimeters. Gravel ranges from 0 to 15 percent by volume in the solum and from 0 to 40 percent in the substratum. Some pedons have up to 15 percent cobbles in the substratum. Unless limed, reaction ranges very strongly acid to slightly acid.

The A or Ap horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 1 to 4. Texture is loam, very fine sandy loam, fine sandy loam, or sandy loam. It has weak or moderate granular structure and is friable or very friable.

The Bw horizon has hue of 10YR to 5Y and value and chroma of 3 to 6. Iron depletions occur above a depth of 60 centimeters. The Bw horizon is dominantly fine sandy loam or sandy loam, but includes thin strata of loam, very fine sandy loam, or silt loam. It has granular or subangular blocky structure, or the horizon is massive. Consistence is friable or very friable.

Some pedons have thin Ab horizon strata.

The C horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 1 to 6. It is typically has redoximorphic features in some subhorizon. Texture of individual layers ranges from loamy fine sand to coarse sand in the fine-earth fraction. Included in some pedons are thin loamy and/or extremely gravelly strata. Also, some pedons have a loamy C horizon layer just below the Bw horizon. The C horizon is single grain and loose in the sandy part. The loamy part is typically massive and friable or very friable. The thickness and number of subhorizons is variable and corresponds to the thickness and variability of the alluvial deposits.

COMPETING SERIES: The Basher, Iotla, Issue, and Philo series are currently in the same family. Iotla and Issue series are from outside LRRs L, R and S. Basher soils have hue of 7.5YR or redder in the B horizon. Philo soils formed in alluvium derived from sandstone and shale. Iotla soils have redoximorphic features in the upper part of the B horizon. Issue soils are somewhat poorly drained. Iotla and Issue soils also have mean summer temperatures more than 3 degrees Celsius warmer than Pootatuck soils.

GEOGRAPHIC SETTING: Pootatuck soils are nearly level soils on floodplains and along rivers and streams. Slope ranges from 0 to 3 percent. The soils formed in recent alluvium derived mostly from granite, gneiss, and schist. Mean annual temperature ranges from 7 to 13 degrees Celsius, mean annual precipitation ranges from 890 to 1270 millimeters, but the range includes as low as 660 millimeters in some places east of Adirondack Mountains in the Champlain Valley

of New York. The growing season ranges from 115 to 190 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Ellington, Ninigret, Occum, Rippowam, Tisbury, and Winooski soils and the Agawam, Enfield, Hadley, Haven, Hinckley, Lim, Limerick, Merrimac, Saco, Suncook, and Windsor soils on nearby landscapes. The well drained Occum and the poorly drained Rippowam soils are associated in a drainage sequence. Agawam, Enfield, Haven, Hinckley, Merrimac, and Windsor soils are better drained and are on nearby outwash terraces. Hadley, Lim, Limerick, and Saco soils are silty floodplain associates. Suncook soils are sandy, excessively drained soils on floodplains.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Moderately well drained. Surface runoff is slow. Saturated hydraulic conductivity moderately is moderately high or high in the loamy upper layers and high or very high in the sandy substratum. Most areas of these soils flood for short periods each year. Soils on higher positions flood occasionally.

USE AND VEGETATION: Cleared areas are used for cultivated crops, hay, or pasture. Common trees in wooded areas are white pine, white, yellow, and gray birch, red maple, elm, alder, and hemlock.

DISTRIBUTION AND EXTENT: Floodplains in Connecticut, Massachusetts, New Hampshire, eastern New York, Rhode Island, and Vermont; MLRAs 142, 144A and 145. The series is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts

SERIES ESTABLISHED: Fairfield County, Connecticut, 1979.

REMARKS: Cation exchange activity class placement determined from a review of limited lab data and similar or associated soils.

Diagnostic horizons and features recognized in this pedon are:
1. Ochric epipedon - the zone from 0 to 10 centimeters (A horizon).
2. Cambic horizon - the zone from 10 to 74 centimeters (Bw horizons).
3. Fluvaquentic subgroup - irregular decrease in organic carbon with depth and organic carbon is greater than 0.2 percent within 1.25 meters; aquic conditions and low chroma redoximorphic depletions with chroma 2 or less are within a depth of 60 centimeters from the surface.
4. Particle-size class - averages coarse-loamy in the control section from 25 to 100 centimeters.

RIPPOWAM SERIES

The Rippowam series consists of very deep, poorly drained loamy soils formed in alluvial sediments. They are nearly level soils on flood plains subject to frequent flooding. Slope ranges from 0 to 3 percent. Saturated hydraulic conductivity ranges from moderately high or high in the loamy upper part and high or very high in the underlying sandy materials. Mean annual temperature is about 50 degrees F., and mean annual precipitation is about 47 inches.

TAXONOMIC CLASS: Coarse-loamy, mixed, superactive, nonacid, mesic Fluvaquentic Endoaquepts

TYPICAL PEDON: Rippowam fine sandy loam in woodland at an elevation of about 435 feet. (Colors are for moist soil.)

A--0 to 5 inches; very dark grayish brown (10YR 3/2) fine sandy loam; weak medium granular structure; friable; common fine and medium roots; very strongly acid; clear wavy boundary. (3 to 9 inches thick)

Bg1--5 to 12 inches; dark grayish brown (10YR 4/2) fine sandy loam; weak medium subangular blocky structure; friable; common fine and medium roots; common medium prominent strong brown (7.5YR 5/6) masses of iron accumulation; very strongly acid; clear wavy boundary.

Bg2--12 to 19 inches; dark gray (10YR 4/1) fine sandy loam; weak medium subangular blocky structure; friable; few fine and medium roots; many medium prominent yellowish red (5YR 4/6) masses of iron accumulation; strongly acid; clear wavy boundary. (Combined thickness of the Bg horizons is 6 to 27 inches.)

BCg1--19 to 24 inches; grayish brown (10YR 5/2) sandy loam; massive; friable; few fine and medium roots; common medium prominent strong brown (7.5YR 5/6) masses of iron accumulation; strongly acid; clear wavy boundary.

BCg2--24 to 27 inches; very dark gray (10YR 3/1) sandy loam; massive; friable; few fine and medium roots; moderately acid; clear wavy boundary. (Combined thickness of the BCg horizons is 0 to 8 inches.)

Cg1--27 to 31 inches; dark gray (10YR 4/1) loamy sand; single grain; loose; moderately acid; clear wavy boundary.

Cg2--31 to 65 inches; grayish brown (10YR 5/2) very gravelly sand; single grain; loose; 35 percent gravel; moderately acid.

TYPE LOCATION: Fairfield County, Connecticut; town of Redding, 100 feet south of Cross Highway and 100 feet east of Little River. USGS Botsford Quadrangle; latitude 41 degrees 18 minutes 32 seconds N. and longitude 73 degrees 21 minutes 57 seconds W., NAD 27.

RANGE IN CHARACTERISTICS: Solum thickness ranges from 20 to 40 inches. The difference between mean summer soil temperature and mean winter soil temperature is at least 25 degrees F. or more. Depth to the coarse-textured substratum layers commonly is from 20 to 40 inches but can range to a depth of 45 inches. Gravel ranges from 0 to 15 percent by volume in the solum and from 0 to 40 percent in the sandy substratum. Some pedons have up to 10 percent cobbles in the coarse-textured substratum. Reaction ranges from very strongly acid to neutral with some subhorizon being moderately acid, slightly acid, or neutral within a depth of 40 inches.

Some pedons have an O horizon that is highly decomposed, moderately decomposed, or slightly decomposed plant material. It has hue of 5YR to 10YR and value and chroma of 3 or less.

The A or Ap horizon has hue of 10YR or 2.5Y, value of 2 to 4, and chroma of 1 or 2. Texture is very fine sandy loam, fine sandy loam, or sandy loam. It typically has weak or moderate granular structure but some pedons have subangular blocky structure. Consistence is friable or very friable.

The Bg horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 1 or 2 and typically has redoximorphic features. Texture of the Bg horizon is dominantly fine sandy loam or sandy loam. The Bg horizon is massive or has weak granular or subangular blocky structure. Consistence is friable or very friable.

The BCg horizon, where present, has hue of 10YR to 5Y, value of 3 to 6, and chroma of 1 or 4 and typically has redoximorphic features. Texture of the BCg horizon is dominantly fine sandy loam or sandy loam. The BCg horizon is massive or has weak granular or subangular blocky structure. Consistence is friable or very friable.

Included in some pedons are thin Ab horizons with characteristics similar to the A horizon.

The C horizon or layer has hue of 10YR to 5Y, value of 3 to 6, and chroma of 1 to 4. Texture ranges from loamy fine sand to coarse sand in the fine-earth fraction. The C horizon is typically single grain and loose. Some pedons have thin loamy strata and/or extremely gravelly strata in the lower part of the C horizon.

COMPETING SERIES: There are no soils currently in the same family. Briscot, Holderton, and Lim soils are in related families. Briscot soils are from outside LRR R.

Briscot soils are dominantly fine sandy loam or finer to a 60-inch depth and the difference between mean summer soil temperature and mean winter soil temperature is less than 25 degrees

F. Holderton soils have an active cation exchange activity class and have textures finer than loamy fine sand in the substratum. Lim soils have a texture to a depth of at least 18 inches that is commonly silt loam or very fine sandy loam but includes loam with more than 65 percent silt plus very fine sand.

GEOGRAPHIC SETTING: Rippowam soils are nearly level soils on flood plains along rivers and streams. They are in low areas. Slope ranges from 0 to 3 percent. The soils formed in recent alluvium derived mostly from granite, gneiss, and schist. Mean annual temperature ranges from 45 to 54 degrees F., mean annual precipitation ranges from 35 to 50 inches, and the growing season ranges from 115 to 190 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Agawam, Enfield, Hadley, Haven, Hinckley, Lim, Limerick, Merrimac, Ninigret, Occum, Pootatuck, Saco, Suncook, Tisbury, Windsor, and Winooski soils on nearby landscapes. The well drained Occum and the moderately well drained Pootatuck soils are associated in a drainage sequence. Agawam, Haven, Enfield, Hinckley, Merrimac, Ninigret, Tisbury, and Windsor soils are better drained soils on outwash terraces. Hadley soils are well drained silty floodplain associates. Suncook soils are excessively drained sandy soils on floodplains.

DRAINAGE AND PERMEABILITY: Poorly drained. Surface runoff is negligible to low. Saturated hydraulic conductivity ranges from moderately high or high in the loamy upper part and high or very high in the underlying sandy materials. These soils typically flood in the spring of each year. Rippowam soils have a water table at or near the surface much of this year.

USE AND VEGETATION: Most areas are in brushy woodland. Common trees are red maple, willow, and alder. A few areas are cleared and used for pasture or hay.

DISTRIBUTION AND EXTENT: Floodplains in Connecticut, Massachusetts, New Hampshire, eastern New York, Rhode Island, and Vermont; MLRAs 142, 144A, 145. The series is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Fairfield County, Connecticut, 1979.

REMARKS: This revision reflects conformance to a change in soil taxonomy based on a revision to the definition of the cambic horizon made in 1999. Cation exchange activity class placement determined from a review of limited lab data and similar or associated soils.

Diagnostic horizons and features recognized in this pedon are:

1. Ochric epipedon - the zone from 0 to 5 inches (A horizon).
2. Cambic horizon - the zone from 5 to 27 inches (Bg1, Bg2, BCg1, and BCg2 horizons). Evidence of alteration is in the form of description of subangular blocky structure and inferred

absence of rock structure to a depth of 27 inches.
3. Particle-size class - averages coarse-loamy in the control section from 10 to 40 inches.

SACO SERIES

The Saco series consists of very deep, very poorly drained soils formed in silty alluvial deposits. They are nearly level soils on flood plains, subject to frequent flooding. Slope ranges from 0 to 2 percent. Permeability is moderate in the silty layers and rapid or very rapid in the underlying sandy materials. Mean annual temperature is about 50 degrees F. and mean annual precipitation is about 47 inches.

TAXONOMIC CLASS: Coarse-silty, mixed, active, nonacid, mesic Fluvaquentic Humaquepts

TYPICAL PEDON: Saco silt loam - grass field. (Colors are for moist soil unless otherwise noted.)

A--0 to 12 inches; very dark gray (10YR 3/1) silt loam; gray (10YR 5/1) dry; weak coarse granular structure; very friable; many fine roots; moderately acid; clear wavy boundary. (10 to 15 inches thick)

Cg1--12 to 32 inches; gray (10YR 5/1) silt loam; massive; friable; few fine roots; common medium faint light brownish gray (10YR 6/2) iron depletions and common medium prominent strong brown (7.5YR 5/8) masses of iron accumulation; moderately acid; clear wavy boundary.

Cg2--32 to 48 inches; gray (5Y 5/1) silt loam with thin strata of very dark gray (10YR 3/1) silt loam; massive; friable; moderately acid; clear wavy boundary. (Combined thickness of the silty C horizon layers is 30 to 50 inches)

2Cg3--48 to 60 inches; gray (10YR 6/1 and 5/1) stratified coarse sand and medium sand; single grain; loose; moderately acid.

TYPE LOCATION: Hartford County, Connecticut; town of South Windsor, 1200 feet west along Newbury Road from the intersection with Ter Street and 270 feet south of Newbury Road. USGS Manchester quadrangle; latitude 41 degrees 49 minutes 49 seconds N., Longitude 72 degrees 37 minutes 23 seconds W., NAD 27.

RANGE IN CHARACTERISTICS: Depth to the coarse-textured substratum layers is more than 40 inches. Gravel ranges from 0 to 5 percent to 40 inches and from 0 to 40 percent below. The soil is strongly acid to neutral to a depth of about 30 inches and moderately acid to neutral below.

Some pedons have O horizons up to 5 inches thick.

The A or Ap horizon has hue of 7.5YR through 2.5Y, value of 2 or 3 and chroma of 1 through 3. Texture is silt loam, mucky silt loam, very fine sandy loam or mucky very fine sandy loam. It has weak granular structure or the horizon is massive. Consistence is friable or very friable.

Individual layers of the C horizon are neutral or have hue of 10YR through 5Y, value of 3 through 6 and chroma of 0 through 2. Layers within a 30 inch depth commonly have value of 5 or 6 and chroma of 1 or 2 and have redoximorphic features. Included in some pedons are thin, Ab horizon strata. Texture of the C horizon to a depth of 40 inches or more is silt loam or very fine sandy loam. Below 40 inches texture ranges to include loamy fine sand through very gravelly coarse sand. Some pedons have subhorizons with texture of fine sandy loam. The upper silty layers are massive or have weak structure. Consistence is friable or very friable. The underlying sandy layers are single grain and loose. The thickness and number of horizons below the A horizon is variable and corresponds to the thickness and variability of the alluvial deposits.

COMPETING SERIES: There are no other series currently in the same family.

The Birdsall, Mansfield, Rippowam, Wayland and Whitman soils are similar soils in related families.

Birdsall, Mansfield and Whitman soils have a regular decrease in organic-carbon with depth. In addition, Mansfield and Whitman soils are coarse-loamy. Wayland soils have a dark A horizon less than 10 inches thick and are fine-silty. Rippowam soils are coarse-loamy and poorly drained.

GEOGRAPHIC SETTING: Saco soils are nearly level soils on flood plains, along rivers and streams. They are in depressed areas. Slope ranges from 0 to 2 percent. The soils formed in recent silty alluvium derived mostly from granite, gneiss, schist, shale and sandstone. Mean annual temperature is 45 to 54 degrees F., mean annual precipitation is 32 to 50 inches and the growing season is 120 to 195 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Agawam, Bash, Enfield, Hadley, Haven, Hinckley, Limerick, Merrimac, Ninigret, Occum, Pootatuck, Rippowam, Suncook, Tisbury, Windsor and Winooski soils on nearby landscapes. The well drained Hadley, moderately well drained Winooski and poorly drained Limerick soils are associated in a drainage sequence. Agawam, Enfield, Haven, Hinckley, Merrimac, Ninigret, Tisbury, and Windsor soils are better drained soils on nearby outwash terraces. Bash, Occum, Pootatuck and Suncook soils are coarser textured flood plain associates.

DRAINAGE AND PERMEABILITY: Very poorly drained. Surface runoff is slow or very slow. In places water is ponded on the surface from late fall through early spring. Permeability is moderate in the silty layers and rapid or very rapid in the underlying sandy materials. These soils flood in the spring and after periods of heavy rainfall.

USE AND VEGETATION: Most areas are in brushy woodland. Common trees are red maple, elm, willow, pin oak, and alder. Fir and spruce are common in the northern areas. A few areas are in low quality pasture.

DISTRIBUTION AND EXTENT: Floodplains in Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, Vermont and eastern New York; MLRAs 101, 142, 144A, and 145. The series is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts

SERIES ESTABLISHED: Cumberland County, Maine, 1915.

REMARKS: This revision reflects change in soil taxonomy and general updating. Cation exchange activity class placement determined from a review of limited lab data and similar or associated soils. Saco soils were previously used in Maine but soil temperature studies have resulted in the mesic soil temperature regime not being used currently.

Diagnostic horizons and features recognized in this pedon are:

1. Umbric epipedon - the zone from 0 to 12 inches (A);
2. Fluvaquentic subgroup - an irregular decrease in organic-carbon content between a depth of 25 cm. and 125 cm. and slope less than 25 percent;
3. Particle size class - averages coarse-silty in the control section 10 to 40 inches.

National Cooperative Soil Survey

LOCATION SCARBORO MA CT NH NY RI VT
Established Series
Rev. WHT-SMF-MFF
03/2010

SCARBORO SERIES

The Scarboro series consists of very deep, very poorly drained soils in sandy glaciofluvial deposits on outwash plains, deltas, and terraces. They are nearly level soils in depressions. Slope ranges from 0 through 3 percent. Saturated hydraulic conductivity is high or very high. Mean annual temperature is about 49 degrees F. (9 degrees C.) and the mean annual precipitation is about 44 inches (1118 millimeters).

TAXONOMIC CLASS: Sandy, mixed, mesic Histic Humaquepts

TYPICAL PEDON: Scarboro mucky fine sandy loam woodland; in an area of Scarboro mucky fine sandy loam at an elevation of about 212 meters. (Colors are for moist soil.)

Oi-- 0 to 1 inch (0 to 3 centimeters); slightly decomposed maple leaves and other plant material

Oa-- 1 to 8 inches (3 to 20 centimeters); dark brown (10YR3/3) mucky peat; thin platy structure; friable; common fine roots; very strongly acid; abrupt wavy boundary. (Combined thickness of Oi, Oe, and Oa horizons is 8 to 13 inches (20 to 33 centimeters).)

A-- 8 to 14 inches (20 to 36 centimeters); black (N 2/0) mucky fine sandy loam; weak medium granular structure; friable; common fine roots; very strongly acid; abrupt smooth boundary. (0 to 14 inches (0 to 36 centimeters) thick.)

Cg1-- 14 to 19 inches (36 to 48 centimeters); grayish brown (2.5Y 5/2) loamy sand; massive; friable; many fine roots; very strongly acid; abrupt irregular boundary.

Cg2-- 19 to 22 inches (48 to 56 centimeters); grayish brown (2.5Y 5/2) sand; massive; friable; few fine roots; 10 percent rock fragments; common medium prominent dark brown (7.5YR 3/2) areas of iron depletion and common medium prominent yellowish red (5YR 4/6) masses of iron; very strongly acid; clear wavy boundary.

Cg3-- 22 to 65 inches (56 to 165 centimeters); grayish brown (2.5Y 5/2) gravelly sand; single grain; loose; 15 percent rock fragments; strongly acid.

TYPE LOCATION: 60 feet north of Electric Avenue near the south edge of Forest Hill Cemetery in the City of Fitchburg, Massachusetts. USGS Fitchburg, MA topographic quadrangle, Latitude 42 degrees, 34 minutes, 0.3 seconds N., and Longitude 71 degrees, 48 minutes, 33.3 seconds W., NAD 1983.

RANGE IN CHARACTERISTICS: Stones range from 0 through 5 percent by volume in the A horizon and upper part of the C horizon and are absent in the lower part of the C horizon. Cobbles range from 0 through 10 percent in the A horizon, 0 through 5 percent in the upper part of the C horizon, and are absent in the lower part of the C horizon. Gravel ranges from 0 through 10 percent by volume in the A horizon, 0 through 20 percent in the upper part of the C horizon to a depth of 30 inches (76 centimeters), and 0 through 50 percent in the C horizon below a depth of 30 inches (76 centimeters). Reaction ranges from very strongly acid through moderately acid in the A horizon and upper part of the C horizon, and from very strongly acid through neutral in the lower part of the C horizon.

The O horizon is commonly mucky peat or muck, but the range includes thin layers of peat at the surface. The O horizon is neutral or has hue 5YR through 10YR, value of 2 or 3, and chroma of 0 through 3.

The A horizon where present is neutral or has hue of 5YR through 2.5Y, value of 2 through 3, and chroma of 0 through 2. It is fine sandy loam, sandy loam, loamy fine sand, loamy sand, fine sand, sand or their mucky analogues in the fine-earth fraction. This horizon commonly is 5 through 14 inches (13 through 36 centimeters) thick, but in some places may be less than 5 inches (13 centimeters) thick or absent.

The upper part of the Cg horizon is neutral or has hue of 10YR through 5Y, value of 3 through 7, and chroma of 0 through 3. Some pedons have few or common fine through coarse redoximorphic features. Texture is fine sandy loam, sandy loam, loamy fine sand, loamy coarse sand, loamy sand, fine sand, or sand in the fine-earth fraction.

The lower part of the C horizon is neutral or has hue of 10YR through 5Y or 5GY, value of 3 through 6, and chroma of 0 through 4. Redoximorphic features range from none through many and are fine through coarse. Texture is loamy fine sand, loamy sand, fine sand, sand, loamy coarse sand, or coarse sand in the fine-earth fraction. The C horizon is structureless and loose, very friable, or friable. It is often stratified.

COMPETING SERIES: These are the Ackerman and Antung series. These soils are from outside LRR R and S. Ackerman soils are more alkaline in the organic horizons and the upper part of the C horizon. They also contain coprogenous material. Antung soils are more alkaline and effervesce in the C horizon.

GEOGRAPHIC SETTING: Scarboro soils are in level or nearly level depressions on outwash plains, deltas, and terraces. Slope is less than 3 percent. The soils formed in sandy glaciofluvial deposits. Mean annual temperature ranges from 46 through 57 degrees F. (8 through 14 degrees C.) and mean annual precipitation ranges from 38 through 55 inches (965 through 1397 millimeters).

GEOGRAPHICALLY ASSOCIATED SOILS: The excessively drained Hinckley, Windsor and Penwood soils, somewhat excessively drained Merrimac soils, moderately well drained Sudbury and Deerfield soils, poorly drained Mashpee(T) and Massasoit(T) soils, somewhat poorly and poorly drained Walpole and Wareham soils are on higher positions on associated

glaciofluvial landforms. The poorly drained Rippowam soils and very poorly drained Saco soils are on nearby flood plains. The very poorly drained Rainberry soils lack a Histic epipedon and have Spodic horizons.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Very poorly drained. Saturated hydraulic conductivity is high or very high. Surface runoff is high or very high. The water table is at or near the surface for 6 to 12 months of the year, and many areas are ponded for short periods.

USE AND VEGETATION: Shrub and brush land or woodland. Common shrubs are speckled alder, smooth alder, rhoda azalea, steeplebush spirea, leatherleaf, labrador-tea, winterberry, highbush blueberry, large cranberry, black huckleberry, poison sumac, and sheep laurel. Common trees are red maple, slippery elm, Atlantic white cedar, tamarack, eastern white pine, willow, and gray birch.

DISTRIBUTION AND EXTENT: Glaciofluvial landforms in Connecticut, Massachusetts, New Hampshire, Rhode Island, eastern New York, and Vermont. MLRAs 142, 144A, 145, and 149B. Scarboro soils are extensive.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Cumberland County, Maine; 1915.

REMARKS: 1. Geographical location (latitude and longitude) determined from the published soil survey.

2. The use of the Scarboro series in Maine, and in MLRA 144B, is relict to before temperature classes. These have been removed from the SC file.

Diagnostic horizons and features recognized in this pedon are:
1. Histic epipedon - the zone from the soil surface to a depth of 8 inches (20 centimeters), (Oi and Oa horizons).
2. Thickness of organic soil materials is 8 inches (20 centimeters).
3. Aquic conditions - Histic epipedon or the zone from 19 to 22 inches (48 to 56 centimeters) has 50 percent or more 2 chroma with redox concentrations (Cg2 horizon).

National Cooperative Soil Survey

LOCATION SCIO NY+MA ME NH PA RI

Established Series
Rev. JDV-WEH-DAS
03/2013

SCIO SERIES

The Scio series consists of very deep, moderately well drained soils formed in eolian, lacustrine, or alluvial sediments dominated by silt and very fine sand. They are on terraces, old alluvial fans, lake plains, outwash plains and lakebeds. Saturated hydraulic conductivity is moderately high or high to a depth of 100 centimeters and ranges from moderately low through very high below 100 centimeters. Slope ranges from 0 through 25 percent. Mean annual temperature is 9 degrees C., and mean annual precipitation is 940 millimeters.

TAXONOMIC CLASS: Coarse-silty, mixed, active, mesic Aquic Dystrudepts

TYPICAL PEDON: Scio silt loam, on a 2 percent slope in a pasture. (Colors are for moist soil.)

Ap -- 0 to 23 centimeters; dark grayish brown (10YR 4/2) silt loam; moderate fine granular structure; friable; many fine roots; moderately acid; limed; abrupt smooth boundary. (10 to 33 centimeters thick.)

Bw1 -- 23 to 48 centimeters; yellowish brown (10YR 5/6) silt loam; weak medium subangular blocky structure; friable; common fine roots; common medium and fine pores; strongly acid; clear wavy boundary.

Bw2 -- 48 to 79 centimeters; yellowish brown (10YR 5/4) silt loam; weak fine subangular blocky structure; friable; few fine roots; common medium and fine pores; common medium distinct strong brown (7.5YR 5/6) masses of iron accumulation and light brownish gray (10YR 6/2) areas of iron depletion in the matrix; strongly acid; clear smooth boundary. (Combined thickness of the Bw horizon is 38 to 135 centimeters.)

C -- 79 to 102 centimeters; brown (10YR 5/3) silt loam; very weak thick plate like divisions; friable; common medium and fine pores; many medium prominent yellowish brown (10YR 5/8) masses of iron accumulation and distinct gray (10YR 6/1) areas of iron depletion in the matrix; 3 percent rock fragments; strongly acid; abrupt smooth boundary. (20 to 102 centimeters thick.)

2Cg -- 102 to 183 centimeters; grayish brown (2.5Y 5/2) very gravelly loamy sand; single grain; loose; common medium prominent yellowish brown (10YR 5/6) masses of iron accumulation in the matrix; 35 percent gravel; moderately acid.

TYPE LOCATION: Wyoming County, New York; town of Pike, 2 miles north of village of Pike on west side of Campbell Road, 0.7 mile north of junction of Campbell Road and Safford

Road. USGS Pike, NY topographic quadrangle; Latitude 42 degrees, 35 minutes, 17 seconds N. and Longitude 78 degrees, 09 minutes, 26 seconds W., NAD 1927.

RANGE IN CHARACTERISTICS: Solum thickness ranges from 50 through 168 centimeters. Depth to material contrasting with solum texture is 100 centimeters or more. Depth to bedrock is greater than 1.5 meters. Depth to free carbonates is greater than 2 meters. Rock fragments, mainly gravel and cobbles, range from 0 through 5 percent above 100 centimeters and from 0 through 60 percent below 100 centimeters. Stones cover 0 through 10 percent of the surface in some areas.

Some pedons have an O horizon.

The Ap horizon has hue of 7.5YR or 10YR, value of 3 through 5, and chroma of 2 or 3. It is silt loam, very fine sandy loam, or fine sandy loam. Undisturbed pedons have an A horizon with colors similar to the Ap, but also include value of 2. They are 2 through 5 inches thick. Reaction ranges from extremely acid through strongly acid, unless limed.

The B horizon has hue of 7.5YR through 5Y, value of 4 through 6, and chroma of 3 through 6. Redox depletions and accumulations are within a depth of 24 inches (61 centimeters). It is silt loam or very fine sandy loam. Reaction ranges from extremely acid through strongly acid to a depth of 76 centimeters and very strongly through moderately acid below 76 centimeters. Some pedons have a BC horizon.

The C horizon has hue of 7.5YR through 5Y, value of 4 through 6, and chroma of 1 through 6. Texture is silt loam to fine sandy loam. It may contain strata of gravel and sand. It is massive or single grain, and may have plate-like divisions. Reaction ranges from very strongly acid through slightly alkaline.

The 2C horizon, if present, has hue of 7.5YR through 5Y, value of 3 through 6, and chroma of 1 through 4. It is silt loam, very fine sandy loam, or loamy very fine sand in the fine earth fraction. In addition, below a depth of 40 inches (100 centimeters) it can range from fine sandy loam through very gravelly sand. Reaction ranges from very strongly acid through slightly alkaline.

COMPETING SERIES: The Dartmouth series is the only other series in the same family. Dartmouth soils have a gravel content of 0 through 5 percent throughout, and have below a depth of 40 inches (100 centimeters) textures limited to silt, silt loam, very fine sandy loam, or loamy very fine sand and saturated hydraulic conductivity ranges from moderately low through moderately high.

GEOGRAPHIC SETTING: Scio soils are most commonly on terraces or old alluvial fans, but are also on lake plains, outwash plains, lakebeds, and lacustrine mantled uplands. The solum is formed entirely in eolian, lacustrine, or alluvial sediments which may extend to a depth of many centimeters or may be underlain by loamy, sandy, or gravelly material at depths greater than 40 inches (100 centimeters). Slope ranges from 0 through 25 percent. Mean annual temperature ranges from 8 through 10 degrees C., mean annual precipitation ranges from 710 through 1270 millimeters, and mean annual frost-free days ranges from 120 through 180 days. Elevation

ranges from 31 through 457 meters above sea level.

GEOGRAPHICALLY ASSOCIATED SOILS: The Scio series is in a drainage sequence with the well drained Unadilla soils, the well drained and moderately well drained Bridgehampton soils, the poorly drained Raynham soils, and the very poorly drained Birdsall soils. Pope, Tioga, and Hadley soils, and their wetter associated soils are on adjacent floodplains. Alton, Chenango, Copake, and Howard soils, and their wetter associated soils are on adjacent gravelly outwash terraces, kames, and outwash plains.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Moderately well drained. The potential for surface runoff is very low to high. Saturated hydraulic conductivity is moderately high or high to a depth of 100 centimeters and ranges from moderately low through very high below 40 inches 100 centimeters.

USE AND VEGETATION: Most of the soil has been cleared and is used for growing hay, corn, vegetables, fruit, and small grain. Native vegetation is northern red oak, white ash, sugar maple, black cherry, eastern hemlock, and eastern white pine.

DISTRIBUTION AND EXTENT: Massachusetts, Maine, New Hampshire, New York, Pennsylvania, and Rhode Island. MLRAs 101, 139, 140, 143, 144A, 144B, 145, and 149B. The series is moderately extensive.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Allegany County, New York, 1946.

REMARKS: This revision reflects changes to the range in characteristics as well as general updating to metric units. Scio soils have been mapped in frigid areas in the past, but have a Mesic temperature regime. The series will not be used in MLRAs 143 and 144B, or the state of Maine, when older soil surveys in these MLRAs are updated.

Diagnostic horizons and features recognized in this pedon are:
1) Ochric epipedon - the zone from 0 to 23 centimeters (Ap horizon).
2) Cambic horizon - the zone from 23 to 79 centimeters (Bw horizons).
3) Aquic subgroup - Redox depletions with chroma of 2 or less are within 60 centimeters of the mineral soil surface (Bw2 horizon).
4) Particle-size control section - the zone from 23 through 100 centimeters (Bw1, Bw2, C horizons).
5) Lithologic discontinuity - at a depth of 102 centimeters.

ADDITIONAL DATA: Full characterization data for sample no.91MA023009. Pedon analyzed by the NSSL, Lincoln, NE.

SUNCOOK SERIES

The Suncook series consists of very deep, excessively drained sandy soils formed in alluvial sediments. They are nearly level soils on flood plains, subject to frequent or occasional flooding. Slope ranges from 0 to 3 percent. Saturated hydraulic conductivity is high or very high in the surface layer and underlying strata. Mean annual temperature is about 10 degrees Celsius , and mean annual precipitation is about 1090 millimeters.

TAXONOMIC CLASS: Mixed, mesic Typic Udipsamments

TYPICAL PEDON: Suncook loamy fine sand in a woodland at an elevation of about 60 meters. (Colors are for moist soil.)

Ap-- 0 to 18 centimeters; very dark grayish brown (10YR 3/2) loamy fine sand; very weak coarse granular structure; very friable; many fine roots; strongly acid; abrupt smooth boundary. (15 to 25 centimeters thick)

C1-- 18 to 38 centimeters; dark grayish brown (10YR 4/2) and brown (10YR 5/3) coarse sand; single grain; loose; few fine roots; 2 percent fine gravel; strongly acid; abrupt smooth boundary.

C2-- 38 to 56 centimeters; dark brown (10YR 3/3) loamy fine sand with lenses of coarse sand; single grain; loose; few fine roots; strongly acid; abrupt smooth boundary.

C3-- 56 to 81 centimeters; pale brown (10YR 6/3) medium and coarse sand; single grain; loose; strongly acid; abrupt smooth boundary.

C4-- 81 to 107 centimeters; dark grayish brown (10YR 4/2) fine and medium sand; single grain; loose; strongly acid; abrupt smooth boundary.

C5-- 107 to 165 centimeters; dark grayish brown (10YR 4/2) stratified sand; single grain; loose; 10 percent gravel; strongly acid. (Combined thickness of the C horizons is 140 to 150 cm within a depth of 165 cm).

TYPE LOCATION: Hartford County, Connecticut; Town of Granby, 1000 feet east along Mechanicsville Road from the intersection with Connecticut Route 189, 1200 feet north of Mechanicsville Road, and 50 feet east of the East Branch Salmon Brook; USGS Tariffville topographic quadrangle, latitude 41 degrees 58 minutes 26 seconds N., longitude 72 degrees 48 minutes 12 seconds W., NAD 27.

RANGE IN CHARACTERISTICS: Most pedons are essentially gravel free, but the range includes as much as 10 percent gravel by volume to a 50 centimeter-depth, up to 20 percent gravel from 50 to 100 centimeters, and as much as 40 percent below a depth of 100 centimeters. Unless limed, reaction ranges from very strongly acid to slightly acid.

The Ap or A horizon has hue of 10YR or 2.5Y, value of 2 to 4, and chroma of 1 to 3. Texture is loamy sand, loamy fine sand, sandy loam, or fine sandy loam. The horizon commonly has weak or moderate granular structure or it is single grain. Some pedons have subangular blocky structure. Consistence is friable, very friable or loose. A horizons may be less than 15 centimeters thick in some places.

Individual layers of the C horizon have hue of 7.5YR to 5Y, value of 3 to 6, and chroma of 1 to 6. Texture ranges from loamy fine sand to coarse sand in the fine-earth fraction.
Some pedons have thin buried sandy A horizons that are very dark grayish brown to black.

COMPETING SERIES: These are the Acquango, Aldo, Bigapple, Biltmore, Boplain, Breeze, Caesar, Chute, Dabney, Gardiner, Hodge, Oakville, Osolo, Pahuk, Penwood, Perks, Pinegrove, Plainfield, Poquonock, Ronda, Samoa, Sardak, Sarpy, Scotah, Spessard, Tyner, Wapanucket, and Windsor soils.
Acquango, Biltmore, Gardiner, Pahuk, Samoa, Sarduk, and Sarpy soils are from outside LRR R and S. Acquango soils are very slightly to moderately saline. Aldo soils have a water table and saturation within the series control section for as much as 1 month per year in 6 or more out of 10 years. Bigapple and Breeze soils formed in anthrotransported materials. Biltmore and Spessard soils are well drained. Boplain soils have a paralithic contact within the control section. Caesar, Oakville, Penwood, Plainfield, Tyner, and Windsor soils have B horizons. Chute, Hodge, and Sarpy soils are neutral to moderately alkaline throughout. Dabney and Westport soils receive more than 1500 centimeters of precipitation. Osolo soils have sola thicker than 150 centimeters. Pahuk soils formed in old alluvium and outwash and are not subject to flooding. Perks soils have high chroma mottles within a depth of 100 centimeters. Pinegrove soils formed in acid regolith from surface mine operations. Poquonuck soils have densic horizons within 100 centimeters. Samoa soils formed in eolian materials. Sardak soils are calcareous. Scotah soils have redoximorphic features at depths of 100 to 150 centimeters and saturation for 1 month or less per year in 6 out of 10 years. Ronda soils formed on floodplains of the mesic Piedmont region of North Carolina. Wapanucket soils formed in sandy glaciofluvial or eolian deposits underlain by loamy glaciolacustrine deposits.

GEOGRAPHIC SETTING: Suncook soils are nearly level soils on flood plains. Slope ranges from 0 to 3 percent. The soils formed in recent sandy alluvium derived mainly from granite, gneiss, schist, and quartzite. Mean annual temperature ranges from 7 to 12 degrees Celsius., mean annual precipitation ranges from 1000 to 1270 millimeters, and the growing season ranges from 120 to 180 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the the Agawam, Hadley, Haven, Hinckley, Lim, Limerick, Merrimac, Occum, Pootatuck, Rippowam, Saco, Windsor, and Winooski soils on nearby landscapes. The well drained Occum, moderately well drained

Pootatuck, and poorly drained Rippowam soils are associated in a drainage sequence. Other floodplain associates include the Hadley, Winooski, Lim, Limerick, and Saco soils, all of which have higher silt content. Agawam, Haven, Hinckley, and Merrimac soils are on nearby outwash terraces and are underlain by stratified sand and gravel.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Excessively drained. Surface runoff is negligible. Saturated hydraulic conductivity is high or very high throughout. Flooding varies from once a year to once in ten years, but typically does not occur in the growing season.

USE AND VEGETATION: Most areas are wooded or in brushy unimproved pasture. Cleared areas are in hay or pasture, but a few scattered areas are in cultivated crops. Common trees are sycamore, aspen, cotton wood white and black oak, silver maple red maple, white pine, and ironwood. Understory plants include bayberry, ground cedar, lowbush blueberry, pipsissewa, and hairy moss.

DISTRIBUTION AND EXTENT: Flood plains in Connecticut, Massachusetts, New Hampshire, New York, and Rhode Island; MLRAs 140, 144A, 145, 149A, and 149B. The series is of small extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts

SERIES ESTABLISHED: Hartford County, Connecticut, 1959.

REMARKS: This revision reflects general updating.
Diagnostic horizons and features recognized in this pedon include:
1. Ochric epipedon the zone from 0 to 18 centimeters (Ap horizon)
2. Particle-size class - the control section from 25 to 100 centimeters averages sandy (C1, C2, C3, and C4 horizons).
3. Entisols - no diagnostic horizons present.
4. Udic moisture regime and the mean summer and mean winter soil temperatures at a depth of 50 centimeters differ by 5 degrees Celsius or more.

LOCATION SWANSEA MA+RI

Established Series
Rev. PCF-DGG-DAS
02/2014

SWANSEA SERIES

The Swansea series consists of very poorly drained organic soils. They formed in 40 to 130 centimeters of highly decomposed organic material over sandy mineral. These soils are in depressions or on flat level areas on uplands and outwash plains. Saturated hydraulic conductivity is moderately high or high in the organic material and very high in the substratum. The mean annual temperature is about 9 degrees Celsius and the mean annual precipitation is about 1143 millimeters.

TAXONOMIC CLASS: Sandy or sandy-skeletal, mixed, dysic, mesic Terric Haplosaprists

TYPICAL PEDON: Swansea muck - on a 0 percent slope in a wooded area. When described the soil was wet and the depth to the water table was 4 inches. (Colors are for moist soils.)

Oa1--0 to 5 cm.; dark reddish brown (5YR 2/2) broken face and rubbed muck (sapric material); 15 percent fiber, 2 percent rubbed; weak medium granular structure; very friable; many medium roots; less than 5 percent mineral; extremely acid; abrupt wavy boundary.

Oa2--5 to 23 cm.; black (5YR 2/1) broken face and rubbed sapric material; 10 percent fiber, 2 percent rubbed; weak medium granular structure; very friable; common medium roots; less than 5 percent mineral; extremely acid; abrupt wavy boundary.

Oa3--23 to 33 cm.; black (N 2/) broken face and rubbed sapric material; 10 percent fiber, 2 percent rubbed; massive; very friable; few fine roots; contains 5 percent brown (7.5YR 4/4) woody fragments 1 to 4 inches in diameter; less than 5 percent mineral; extremely acid; abrupt wavy boundary.

Oa4--33 to 66 cm.; black (N 2/) broken face and rubbed sapric material; 5 percent fiber, 0 percent rubbed; massive; very friable; few fine roots; less than 5 percent mineral; extremely acid; abrupt wavy boundary.

Cg1--66 to 81 cm.; light olive gray (5Y 6/2) loamy coarse sand; single grain; loose; very strongly acid; abrupt wavy boundary.

Cg2--81 to 165 cm.; light olive gray (5Y 6/2) gravelly loamy coarse sand; single grain; loose; 30 percent gravel; very strongly acid.

TYPE LOCATION: Bristol County, Massachusetts, Town of Swansea, 1,000 feet east of Old

Fall River Road, 1,000 feet south of Interstate 295, and 80 feet north of the telephone line. Latitude 41 degrees 45 minutes 57 seconds N. and longitude 71 degrees 14 minutes 49 seconds W., NAD 27.

RANGE IN CHARACTERISTICS: The depth to the Cg horizon is 40 to 130 centimeters. Cumulative layers of hemic materials comprise less than 25 centimeters and fibric materials less than 12 centimeters of the subsurface and bottom tiers. Woody fragments are in some part of the organic material in most pedons and comprise up to 25 percent of some horizons. Fragments consist of twigs, branches, logs, or stumps and are 2 centimeters to more than 30 centimeters in diameter. Woody fragments are firm but break abruptly under pressure. Reaction is less than 4.5 in 0.01 molar calcium chloride throughout the organic material.

The surface tier has hue of 5YR through 10YR, value of 2 or 3, and chroma of 0 to 2. In some pedons the chroma ranges to 4. It is dominantly sapric material; however, in some pedons it has various proportions of both sapric and hemic materials or has fibric materials. It has weak or moderate, fine or medium, granular or subangular blocky structure or it is massive. Some pedons have a mineral surface layer of sand or coarse sand that is 10 to 25 centimeters thick.

The subsurface and bottom tiers, above the C horizon, have hue of 5YR through 10YR, value of 2 to 3, and chroma of 0 to 3. Chroma or value or both may change from 0.5 to 2 units upon rubbing. Broken faces become darker upon brief exposure to air. The subsurface tier is dominated by sapric material with a rubbed fiber content of less than 16 percent of the organic volume. The subsurface and bottom tiers have platy structure or are massive. They are very friable or friable. Unrubbed organic material resembles herbaceous and woody plant tissues.

The C or Cg horizon has hue of 10YR to 5Y, value of 3 to 6, and chroma of 1 to 4. Redoximorphic features are present in some pedons. It ranges from coarse sand to loamy fine sand and their gravelly analogs but may include some finer-textured lenses or horizons in some pedons. Rock fragment content ranges from 0 to 45 percent and is commonly gravel but includes cobbles in some pedons. Reaction ranges from extremely acid to strongly acid.

COMPETING SERIES: This is the Makinen series which are from outside LRR R and S. The Makinen soils receive less than 813 millimeters of mean annual precipitation and have less gravel in the substratum.

Freetown and Paupack are similar soils in related families. Freetown soils have organic layers greater than 130 centimeters. Paupack soils are underlain by loamy skeletal or clayey skeletal mineral material.

GEOGRAPHIC SETTING: Swansea soils are in swamps and bogs that range from small enclosed depressions to areas of several hundred acres in size. They are on outwash plains, till plains and moraines. Slope ranges from 0 to 1 percent. Mean annual temperature is 7 to 10 degrees Celsius and mean annual precipitation is 1016 to 1270 millimeters. The frost-free period is 120 to 180 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Freetown, Hinckley, Windsor,

Ridgebury, Whitman, and Scarboro soils on nearby landscapes. Freetown soils are on similar landscapes and have more than 130 centimeters of organic material. The excessively drained Hinckley and Windsor soils are on nearby outwash landforms. The somewhat poorly and poorly drained Ridgebury soils and the very poorly drained Whitman and Scarboro soils formed in glacial till are adjacent to areas of Swansea soils.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Very poorly drained. Saturated Hydraulic Conductivity is moderately high or high in the organic material and very high in the substratum.

USE AND VEGETATION: Mostly forested. Native vegetation includes red maple, American elm, green ash, eastern hemlock, Atlantic white cedar, buttonbush, winterberry, swamp azalea, and leatherleaf. Some acreage has been cleared and is used for truck crops. The main crop is cranberries.

DISTRIBUTION AND EXTENT: Swamps and bogs in Massachusetts and Rhode Island; MLRAs 144A, 145, 149B. The series is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Bristol County, Massachusetts, 1979

REMARKS: These soils were previously mapped in Massachusetts as Cranberry bog, Medisaprists, and Muck and in some areas as Adrian soils. The Type Location is pedon T1MA603018, also the typical pedon for the soil survey of Bristol County, MA, Southern Part.

Diagnostic horizons and features in this pedon include:

1. Terric feature - mineral soil from a depth of 66 to 165 centimeters (2Cg horizons).
2. Lithic discontinuity - there is a significant change in particle size at a depth of 66 centimeters (Cg1 horizon).
3. Sapric material from 0 to 66 centimeters (Oa horizons)
4. Histic epipedon from 0 to 33 centimeters
5. Aquic conditions 0 to 165 centimeters
6. Endosaturation 0 to 165 centimeters

03/2014

WINDSOR SERIES

The Windsor series consists of very deep, excessively drained soils formed in sandy outwash or eolian deposits. They are nearly level through very steep soils on glaciofluvial landforms. Slope ranges from 0 through 60 percent. Saturated hydraulic conductivity is high or very high. Mean annual temperature is about 10 degrees C and mean annual precipitation is about 1092 mm.

TAXONOMIC CLASS: Mixed, mesic Typic Udipsamments

TYPICAL PEDON: Windsor loamy sand - forested, 3 percent slope, at an elevation of about 24 meters. (Colors are for moist soil.)

Oe--0 to 3 cm; black (10YR 2/1) moderately decomposed forest plant material; many very fine and fine roots; very strongly acid; abrupt smooth boundary. (0 to 8 cm thick.)

A--3 to 8 cm; very dark grayish brown (10YR 3/2) loamy sand; weak medium granular structure; very friable; many very fine and fine roots; strongly acid; abrupt wavy boundary. (3 to 25 cm thick.)

Bw1--8 to 23 cm; strong brown (7.5YR 5/6) loamy sand; very weak fine granular structure; very friable; many fine and medium roots; strongly acid; gradual wavy boundary.

Bw2--23 to 53 cm; yellowish brown (10YR 5/6) loamy sand; very weak fine granular structure; very friable; common fine and medium roots; strongly acid; gradual wavy boundary.

Bw3--53 to 64 cm; light yellowish brown (10YR 6/4) sand; single grain; loose; few coarse roots; strongly acid; clear wavy boundary. (Combined thickness of the Bw horizons is 23 to 86 cm.)

C--64 to 165 cm; pale brown (10YR 6/3) and light brownish gray (10YR 6/2) sand; single grain; loose; few coarse roots; strongly acid.

TYPE LOCATION: Hartford County, Connecticut; town of South Windsor, 1100 feet northwest along Chapel Road from the intersection of Chapel Road and Ellington Road and 100 feet due south of Chapel Road. USGS Manchester, CT topographic quadrangle, Latitude 41 degrees, 48 minutes, 35 seconds N., Longitude 72 degrees, 36 minutes, 22 seconds W., NAD 1983

RANGE IN CHARACTERISTICS: Thickness of the solum ranges from 25 to 92 cm. Rock

fragments, dominantly fine gravel, range from 0 through 10 percent by volume in the solum and from 0 to 15 percent in the substratum. Thin strata of gravel or thin subhorizons of coarse sand or loamy coarse sand are present in some pedons. Unless limed, reaction in the solum commonly is extremely acid to moderately acid, but the range includes slightly acid. Unless limed, reaction in the substratum commonly is very strongly acid to slightly acid, but the range includes neutral.

O horizons are present in some pedons.

The A horizon has hue of 7.5YR or 10YR, value of 2 or 3, and chroma of 1 to 3. Many pedons have an Ap horizon up to 12 inches thick with value of 3 or 4 and chroma of 2 to 4. The A or Ap horizon is loamy fine sand, loamy sand, fine sand, or sand. It has weak or moderate granular structure and is very friable, friable, or loose.

Some pedons have a thin E horizon with hue 7.5YR or 10YR, value of 4 to 6, and chroma of 1 or 2.

The upper part of the Bw horizon has hue of 7.5YR to 2.5Y, value of 4 to 6, and chroma of 4 to 8. The lower part of Bw horizon has hue of 7.5YR to 5Y, value of 4 to 7, and chroma of 3 to 6. The Bw horizon is loamy sand or loamy fine sand in the upper part and loamy fine sand, loamy sand, fine sand, or sand in the lower part. The Bw horizon has weak granular or weak subangular blocky structure, or it is massive or single grain. Consistence is very friable or loose.

Some pedons have a BC horizon similar to the lower part of the Bw horizon.

The C horizon has hue of 5YR to 5Y, value of 4 to 7, and chroma of 1 to 6. It is fine sand, sand, coarse sand, loamy fine sand, or loamy sand. The horizon is massive or single grain and consistence is very friable or loose.

COMPETING SERIES: These are the Acquango, Aldo, Bigapple, Biltmore, Boplain, Breeze, Caesar, Chute, Dabney, Hodge, Oakville, Osolo, Pahuk, Penwood, Perks, Pinegrove, Plainfield, Poquonock, Ronda, Samoa, Sardak, Sarpy, Scotah, Spessard, Suncook, Tyner, and Wapanucket series. Aquango, Aldo, Biltmore, Boplain, Chute, Dabney, Hodge, Osolo, Pahuk, Perks, Ronda, Samoa, Sardak, Spessard, and Tyner soils are from outside of LRRs L, R, and S. Acquango soils are very slightly to moderately saline within the soil profile. Aldo soils have a water table and saturation within the series control section for as much as one month per year in 6 out of 10 years. Bigapple soils formed in human transported soil material from dredging activities. Biltmore and Spessard soils are well drained. Breeze soils formed in human transported sandy soil materials intermingled with construction debris. Caesar soils contain more coarse sand. Chute, Hodge, and Sarpy soils contain free carbonates and do not have a B horizon. Dabney soils do not have a B horizon and receive more than 152 cm of precipitation annually. Oakville soils typically average 50 percent or more fine sand in the subsoil. Osolo soils have a solum thicker than 1.5 m. Penwood soils have hue of 5YR or redder in the B horizon. Pahuk, Perks, Samoa, and Suncook soils do not have a B horizon. Plainfield soils are less moist in all parts of the control section for the 120 days following the summer solstice. Poquonock soils have a densic contact with in 1 m. Ronda soils formed in alluvium from residuum sources. Sardak soils formed in alluvium and are calcareous. Tyner soils have a thicker solum. Wapanucket soils are underlain

by glaciolacustrine deposits with in the series control section.

GEOGRAPHIC SETTING: Windsor soils are nearly level through very steep soils typically on glaciofluvial landforms but include late-Wisconsin-aged dunes. The steeper slopes are typically on terrace escarpments. Slope ranges from 0 to 60 percent. The soils formed in outwash or eolian deposits of poorly graded sands and loamy sands derived mainly from crystalline rocks. Mean annual temperature ranges from 7 to 12 degrees C, and the mean annual precipitation typically ranges from 965 to 1270 mm, but the range includes as low as 660 mm in some places east of Adirondack Mountains in the Champlain Valley of New York. The growing season ranges from 120 to 190 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Deerfield, Hinckley, Merrimac, Quonset, Suncook, Agawam, Hadley, Haven, Occum, Pootatuck, Scarboro, Sudbury, Walpole, Wareham, and Winooski soils on nearby landscapes. The moderately well drained Deerfield and Sudbury, the somewhat poorly drained and poorly drained Walpole and Wareham, and the very poorly drained Scarboro soils are common drainage associates. Agawam and Haven soils are coarse-loamy over sandy or sandy-skeletal or coarse-loamy terrace associates, respectively. Hadley, Occum, Pootatuck, and Winooski soils are on nearby flood plains.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Excessively drained. Surface runoff is negligible to medium. Saturated hydraulic conductivity is high or very high.

USE AND VEGETATION: Most areas are forested or in low growing brushy vegetation. Some areas are used for silage corn, hay, and pasture. Small areas, mostly irrigated, are used for shade tobacco, vegetables and nursery stock. Some areas are in community development. Common trees are white, black, and northern red oak, eastern white pine, pitch pine, gray birch, poplar, red maple, and sugar maple.

DISTRIBUTION AND EXTENT: Late Wisconsin glaciofluvial or eolian landforms in Connecticut, Massachusetts, New Hampshire, New York, Rhode Island, and Vermont; MLRAs 101, 142, 144A, and 145. The series is of large extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Connecticut Valley Area, 1899.

REMARKS: The use of the Windsor series in Maine, and in MLRAs 141, 144B, and 143 is relict to before temperature classes in soil taxoonomy. These have been removed from the SC file.

Diagnostic horizons and features recognized in this pedon include:
1. Ochric epipedon - the zone from 0 to 8 cm (Oe and A horizons).
2. Particle-size class - averages sandy in the control section from 25 to 100 cm.
3. No cambic horizon and development of color - the zone from 8 to 64 cm demonstrates development of color with no illuvial accumulation of material (Bw horizons).

ADDITIONAL DATA: Reference samples from pedons 54MA023005, 63VT011001, 63VT011002, 64NH017003, 64NH017004, 70CT003003, 70MA011003, 70VT017002, 73MA005003, 73MA005004, 91MA023006, 95NH013001, 96NH013004, 98NY045002, 98NY085002, S07VT011004.

LOCATION WINOOSKI MA+CT NH VT

Established Series
Rev. DGG-SMF-DCP
01/2013

WINOOSKI SERIES

The Winooski series consists of very deep, moderately well drained soils formed in alluvial material. These soils are on nearly level flood plains. Slope ranges from 0 through 3 percent. Saturated hydraulic conductivity is moderately low through high. Mean annual precipitation is about 45 inches (1143 millimeters) and the mean annual temperature is about 49 degrees F (7 degrees C).

TAXONOMIC CLASS: Coarse-silty, mixed, superactive, mesic Fluvaquentic Dystrudepts

TYPICAL PEDON: Winooski very fine sandy loam on a 1 percent slope in a cultivated field at an elevation of about 69 meters. (Colors are for moist soil unless otherwise stated.)

Ap -- 0 to 8 inches (0 to 20 centimeters); very dark grayish brown (10YR 3/2) very fine sandy loam; weak fine granular structure; very friable; many fine roots; moderately acid; abrupt smooth boundary. (4 to 18 inches (10 to 46 centimeters thick).

Bw1 -- 8 to 18 inches (20 to 46 centimeters); brown (10YR 4/3) very fine sandy loam; massive; friable; many fine roots; strongly acid; abrupt smooth boundary.

Bw2 -- 18 to 26 inches (46 to 66 centimeters); olive brown (2.5Y 4/4) very fine sandy loam, common medium prominent pinkish gray (5YR 7/2) and faint brown (10YR 5/3) areas of iron depletion; massive; friable; few fine roots; strongly acid; abrupt smooth boundary. (Combined thickness of the Bw horizons is 6 to 30 inches (15 to 76 centimeters).

BC -- 26 to 43 inches (66 to 109 centimeters); olive gray (5Y 5/2) very fine sandy loam; massive; friable; common medium faint light gray (5Y 7/2) areas of iron depletion and faint brown (10YR 5/3) masses of iron accumulation; moderately acid; clear smooth boundary. (0 to 20 inches (0 to 51 centimeters thick).

C -- 43 to 65 inches (109 to 165 centimeters); olive (5Y 5/3) loamy very fine sand; massive; friable; common medium distinct light brownish gray (10YR 6/2) iron depletions and prominent strong brown (7.5YR 5/8) masses of iron accumulation; moderately acid.

TYPE LOCATION: Worcester County, Massachusetts, Town of Lancaster, 100 feet north of Massachusetts Route 117, 900 feet west of the Bolton town line. USGS Hudson, MA topographic quadrangle, Latitude 42 degrees, 27 minutes, 35 seconds N., Longitude 71 degrees, 39 minutes, 7 seconds W., NAD 1983.

RANGE IN CHARACTERISTICS: Solum thickness ranges from 18 through 43 inches (46 through 110 centimeters). Gravel ranges from 0 through 5 percent by volume throughout the soil. Reaction ranges from extremely acid through neutral. Depth to iron depletions with chroma of 2 or less ranges from 14 through 20 inches (35 through 50 centimeters).

The O horizon where present ranges in thickness from 1 or 2 inches (3 through 6 centimeters). The O has hue 7.5YR, value 2.5 or 3, and chroma of 2 or 3. Decompositon of the plant material ranges from fibric through sapric.

The A or Ap horizon has hue of 7.5YR through 5Y, value of 2 through 4, and chroma of 1 through 3. Texture is silt loam, silt, very fine sandy loam, or loamy very fine sand. Structure is subangular blocky, platy, or granular. Consistence is very friable or friable.

Some pedons have Ab and/or AB horizons similar in characteristic to the A or Ap horizon.

The Bw horizon has hue of 7.5 YR through 5Y, value of 2 through 5, and chroma of 2 through 6. Matrix chroma of 2 is below a depth of 20 inches (50 centimeters). Texture is silt loam, silt or very fine sandy loam. Structure is granular or subangular blocky, or it is massive. Consistence is very friable or friable.

The BC horizon, where present, has hue of 10YR through 5Y, value of 2 through 5, and chroma of 2 through 4. Matrix chroma of 2 is below a depth of 20 inches (50 centimeters). Texture is silt loam, silt, very fine sandy loam, or loamy very fine sand. Structure is granular or subangular blocky, or it is massive. Consistence is very friable or friable.

The C horizon has hue of 10YR through 5Y, value of 3 through 6, and chroma of 2 through 4. Matrix chroma of 2 is below a depth of 20 inches (50 centimeters). Texture is silt loam, silt, very fine sandy loam, or loamy very fine sand. Some pedons have thin strata of very fine sand, fine sand, sand, or coarse sand below a depth of 40 inches (100 centimeters). The C horizon is massive or has fine stratification. Consistence is firm through very friable.

The thickness and number of horizons below the A horizon is variable and corresponds to the thickness and variability of the alluvial deposits.

COMPETING SERIES: The Otego soil is the only other soil currently in the same family. Otego soils are formed in alluvium from sandstone, siltstone, and shale. Otego soils do not allow for loamy very fine sand textures in their A, BC, or C horizons.

GEOGRAPHIC SETTING: Winooski soils are nearly level soils on flood plains. They are typically in broad depressions. Slope ranges from 0 through 3 percent. The soils formed in recent alluvial deposits of very fine sand and silt. The source of the alluvium is from igneous and meta-igneous geology, with additions of limestone and dolomite for areas in the Lake Champlain valley, and their resultant glacial materials. Mean annual precipitation ranges from 40 through 50 inches (1016 through 1270 millimeters) and mean annual air temperature from 45 degrees through 52 degrees F. (7 through 11 degrees C.). Mean annual growing season ranges from 120

through 200 days.

GEOGRAPHICALLY ASSOCIATED SOILS: Winooski soils are the moderately well drained member of a drainage sequence which includes the well drained Hadley soils, the poorly drained Limerick soils and the very poorly drained Saco soils on nearby landscapes.

DRAINAGE AND SATURATED HYDRAULIC CONDUCTIVITY: Moderately well drained. Saturated hydraulic conductivity is moderately low through high. Flooding frequency varies from twice a year to once in 10 years. Stream overflow generally occurs during late winter or spring and during periods of high rainfall.

USE AND VEGETATION: Used mainly for growing hay, silage corn and pasture in support of dairying and to some extent for truck crops, potatoes, and tobacco. Native vegetation is forest composed mainly of red maple, silver maple, elm, willow, northern hardwoods, and eastern white pine. Balsam fir and spruce are in the northerly range of the series.

DISTRIBUTION AND EXTENT: New Hampshire, Massachusetts, Connecticut, and Vermont. MLRA's 142, 144A, and 145. The series is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Amherst, Massachusetts.

SERIES ESTABLISHED: Chittenden County, Vermont, 1938.

REMARKS: The Winooski soils mapped in Maine, and in MLRA 144B and 143, are now considered to be in the frigid temperature regime and are relict.

Diagnostic horizons and features recognized in this pedon include:

1. Ochric epipedon - the zone from the surface to a depth of about 8 inches (20 centimeters) (Ap horizon).
2. Coarse-silty particle size - less than 10 percent of the material in the 10 through 40 inch (25 through 100 centimeter) zone is fine sand or coarser, including gravel, and clay averages about 7 percent.
3. Cambic horizon the zone from 8 to 43 inches (20 to 109 centimeters) (Bw1, Bw2, and BC horizons) has evidence of alteration in the form of absence of rock structure or some degree of soil structure.
4. Aquic feature - the zone from 18 to 26 inches has redox depletions and aquic conditions at some time during the year. (Bw2 horizon)

1 Introduction

A radio-telemetry assessment of the downstream passage success for adult silver-phase American eels (*Anguilla rostrata*) was conducted in support of the relicensing for the Lowell Hydroelectric Project (Lowell or Project), Federal Energy Regulatory Commission (FERC) No. 2790, as identified in the Revised Study Plan (RSP) submitted by Boott Hydropower, LLC (Boott) on January 28, 2019. The approach and methodology described in the RSP for the downstream eel passage study was approved with modifications by the FERC in its Study Plan Determination (SPD) letter dated March 13, 2019. In their SPD, FERC staff commented on several points related to the original resource agency study requests and the eel passage study proposed by Boott as part of the PSP.

- Resource agency request for a HI-Z balloon tag turbine survival assessment.
    - *FERC recommended no HI-Z balloon tag assessment be conducted during 2019. Information from the radio-telemetry and desktop analyses should provide adequate estimates of passage route survival. In the event these findings are inconclusive FERC would consider additional study requests.*
- Resource agency request for eel releases to start in mid-September.
    - *FERC recommended that Boott should initiate eel releases as early in the fall season as the commercial collection and associated bacterial and viral screening process prior to import allows.*
- Resource agency request for release of 10 dead tagged eels in conjunction with each upstream release of live tagged eels.
    - *FERC recommended Boott release two dead tagged eels in conjunction with each upstream release of live tagged eels.*
- Resource agency request for two years of radio-telemetry data collection.
    - *FERC noted there was no indication at the time of issuance for the SPD that a second study year was warranted. If the first study year failed to meet study objectives and provide the necessary information for assessing project effects then stakeholders will have an opportunity to file a request to modify the study to collect additional information.*

In accordance with 18 C.F.R. § 5.15(c), Boott filed their Initial Study Report (ISR) with FERC on February 25, 2020. As described in the ISR, data analyses were in progress and scheduled for completion during 2020. On June 12, 2020 FERC issued a Revised Process Plan and Schedule and Determination on Requests for Study Modifications for the Lowell Hydroelectric Project (Revised PPS). In accordance with the Revised PPS, Boott filed their Revised ISR with FERC on September 30, 2020, which contained a full report for the Downstream American Eel Passage

Assessment. Boott held a revised ISR meeting on October 15, 2020 and representatives from FERC, U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), Massachusetts Division of Fisheries and Wildlife (MADFW), Massachusetts Division of Marine Fisheries (MDMF), and the New Hampshire Fish and Game Department (NHFGD) had the opportunity to provide comments. Subsequent to the September 30, 2020 ISR meeting, the MADFW (November 25, 2020), NMFS (November 30, 2020), and MDMF (November 30, 2020) submitted written comments on the ISR to FERC. A summary of comments received and the corresponding responses is provided in Appendix E of this report. Where noted, the body of the report has been updated to reflect the content of those comments.

This final technical report provides a description of the objectives, methodologies and results of the 2019 radio-telemetry assessment to evaluate the downstream passage of adult silver eels at the Lowell Project. In addition to the radio-tagged silver-phase eels marked as part of this evaluation, an additional eel passage study was conducted outside of the Licensing efforts for Lowell to assess downstream movement at the Merrimack River Project (FERC No. 1893). Adult eels tagged as part of the upstream project were also monitored as they moved through the Lowell Project area. Findings for those individuals have been included in this report.

2 Objectives

The goal of this study was to determine the Lowell Project's impact on the outmigration of adult silver-phase American eels.

Specific objectives included:

- Quantification of the movement rates and relative proportion of eels passing via various routes at the project (i.e., turbines, downstream bypass, and spill); and
- Evaluation of mortality of eels passed via each potential route.

3 Project Description and Study Area

The Lowell Project is located at River Mile (RM) 41 on the Merrimack River in the City of Lowell in Middlesex County, Massachusetts, with an impoundment extending approximately 23 miles upstream into Hillsborough County, New Hampshire. The existing Lowell Project consists of: (1) a 1,093-foot-long, 15-foot-high masonry gravity dam (Pawtucket dam) that includes a 982.5-foot-long spillway with a crest elevation of 87.2 feet National Geodetic Vertical Datum 1929 (NGVD 29) topped by 5-foot-high pneumatically-operated crest gates deployed in five independently-operable zones; (2) a 720-acre impoundment with a normal maximum water surface elevation of 92.2 feet NGVD 29; (3) a 5.5-mile-long canal system which includes several small dams and gatehouses; (4) a powerhouse (E.L. Field) which uses water from the Northern Canal and contains two turbine-generator units with a total installed capacity of 15.0 megawatts (MW); (5) a 440-foot-long tailrace channel; (6) four powerhouses (Assets, Bridge Street, Hamilton, and John Street) housed in nineteenth century mill buildings along the Northern and Pawtucket Canal System containing 15 turbine-generator units with a total installed capacity of approximately 5.1 MW; (7) a 4.5-mile long, 13.8-kilovolt transmission line

connecting the powerhouses to the regional distribution grid; (8) upstream and downstream fish passage facilities including a fish elevator and downstream fish bypass at the E.L. Field powerhouse, and a vertical-slot fish ladder at the Pawtucket dam; and (9) appurtenant facilities. At the normal pond elevation of 92.2 feet NGVD 1929 (crest of the pneumatic flashboards), the surface area of the impoundment encompasses an area of approximately 720 acres. The gross storage capacity between the normal surface elevation of 92.2 feet and the minimum pond level of 87.2 feet is approximately 3,600 acre-feet. The Project operates essentially in a run-of-river (ROR) mode using automatic pond level control, and has no usable storage capacity.

The study area for the downstream eel passage assessment included the mainstem Merrimack River from the upper extent of the Project's impoundment located approximately 23 river miles upstream from the Pawtucket Dam in Litchfield, New Hampshire, to the Lawrence Hydroelectric Project (FERC No. 2800), located approximately 11 river miles downstream of the Pawtucket Dam (Figure 3-1). The Upper Pawtucket Canal and Guard Locks facility were also considered as part of the study area.

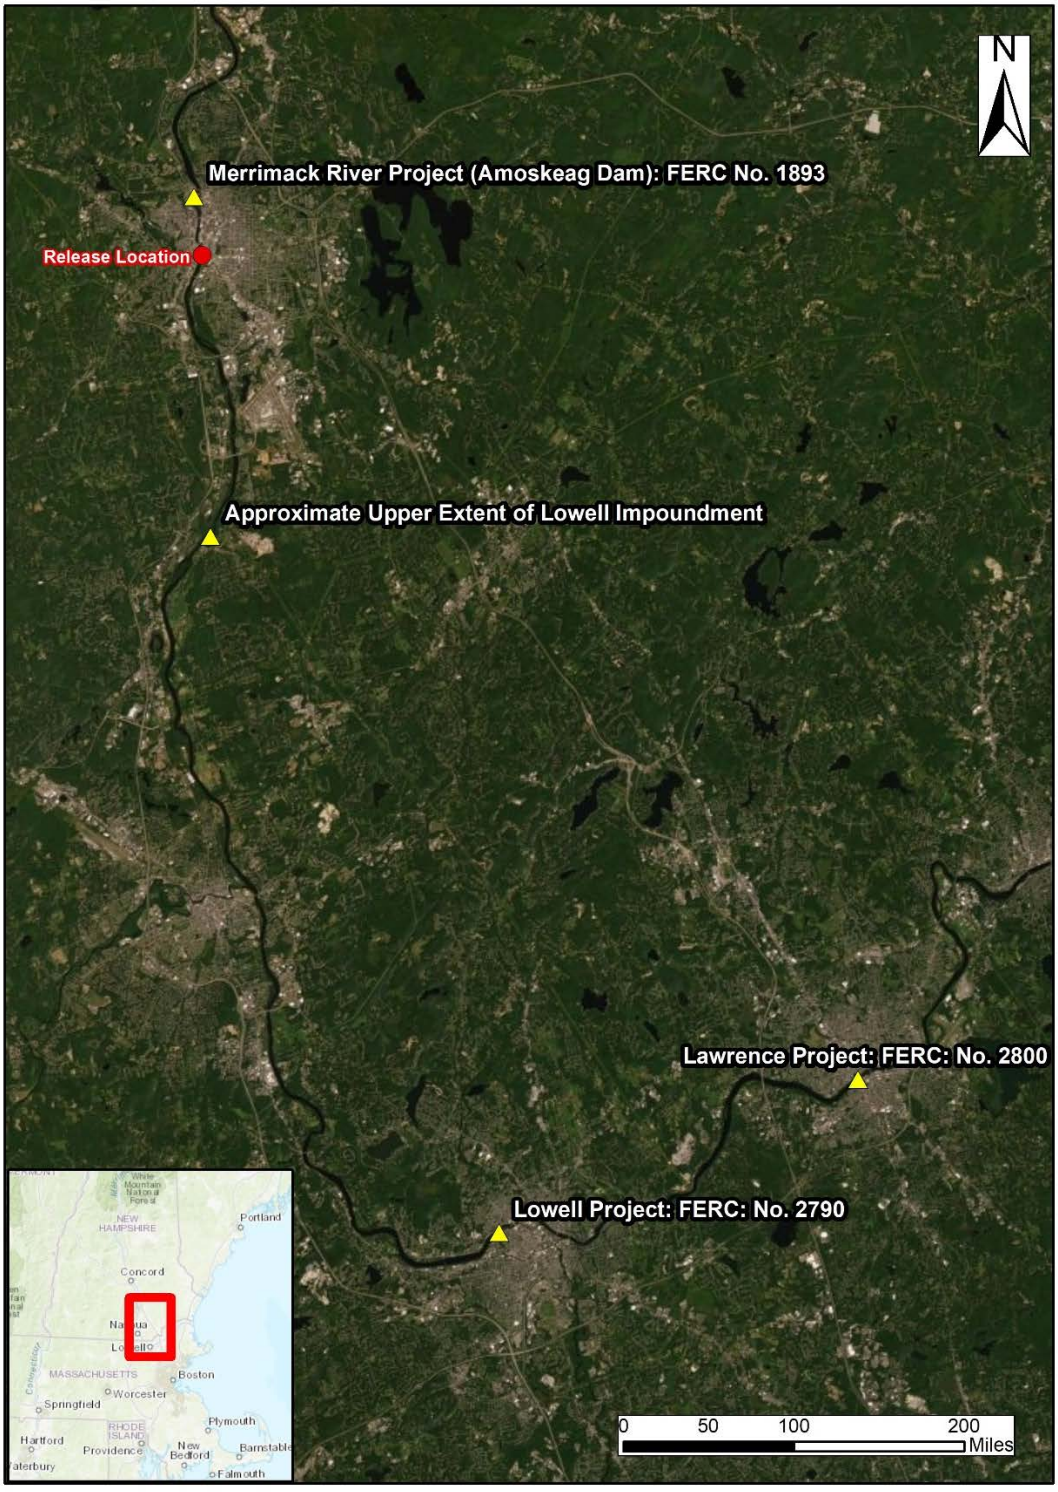

Figure 3–1. Merrimack River study reach considered during the fall 2019 adult silver-phase American eel downstream passage assessment.

4 Methods

Downstream passage of adult American eels through the Lowell Project reach was evaluated via radio-telemetry during the fall of 2019. Following the release of radio-tagged individuals into the Merrimack River upstream of the Lowell impoundment, their movements were monitored using a series of stationary radio-telemetry receivers in place at the Project as well as at several additional stationary monitoring stations installed at bank-side locations upstream and downstream of the Project to inform on general movements, distribution among available passage routes and Project passage success.

4.1 Radio Telemetry Equipment

Movements of radio-tagged individuals during the 2019 study were recorded via a series of stationary radio-telemetry receivers. Radio-telemetry equipment used during the evaluation of downstream passage at Lowell included Orion receivers, manufactured by Sigma Eight, as well as SRX receivers manufactured by Lotek Wireless. Each receiver was paired with either an aerial or underwater antenna (dropper antenna). Aerial antennas (four or six element Yagi) were utilized to detect radio-tagged individuals within the larger, more open sections of river, such as within the tailrace or at locations downriver of Lowell. Dropper antennas were fixed at downstream passage locations (e.g., downstream bypass). Dropper antennas were custom built by stripping the shielded ends of RG-58 coaxial cables.

All eels radio-tagged during 2019 were equipped with a Sigma Eight TX-PSC-I-450 radio transmitter (149.320, 149.340 or 149.360 MHz, pulse rate = 2.0 seconds). The TX-PSC-I-450 transmitters measured approximately 12 x 12 x 46 mm, weighed 8.5 g and had an estimated battery life of 357 days when set at a 2.0 second burst rate. Each transmitter was coded to emit a unique identifying signal so that individual eels could be identified by a receiver.

4.2 Monitoring Stations

The RSP identified a total of twelve monitoring stations to be set up at Lowell for the downstream eel passage assessment. Each of the twelve monitoring locations identified in the RSP were installed as described and each location consisted of a data-logging receiver, antenna, power source, and were configured to receive transmitter signals from a designated area continuously throughout the study period. During installation of each station, range testing was conducted to configure the antennas and receivers in a manner which maximized detection efficiencies at each location. The operation of the radio telemetry receivers was initially established during installation, then confirmed throughout the study period by using beacon tags. A number of beacon tags were stationed at strategic locations within the detection range of either multiple or single antennas, and they emitted signals at programmed time intervals. These signals were detected and logged by the receivers and used to record the functionality of the system throughout the study period.

The locations of monitoring stations installed for the 2019 Lowell eel passage study are outlined here and presented in Figures 4-1 through 4-3.

Monitoring Station 19: This station was installed at the upper end of the Project impoundment and detected eels following their initial movement downstream from the release location and upon entry into the project area. Station 19 consisted of a single Lotek SRX receiver and aerial antenna oriented perpendicular to the river channel.

Monitoring Station 21: This station consisted of a single Lotek SRX radio-receiver and an aerial antenna and was installed and calibrated in a manner to provide detection information for radio-tagged eels as they approached the upstream face of Pawtucket Dam. Detections at this location were used to inform on arrival of eels immediately upstream of the project.

Monitoring Station 25: Station 25 consisted of a single Orion radio-receiver and aerial antenna installed and calibrated to provide coverage of the upstream side of the Pawtucket Gatehouse. This station informed on radio-tagged eels which had approached the upstream side of the Pawtucket Gatehouse.

Monitoring Station 27: Station 27 consisted of a single Lotek radio-receiver and aerial antenna installed and calibrated to provide coverage of the downstream side of the Pawtucket Gatehouse. This station informed on radio-tagged eels which had successfully passed through the Pawtucket Gatehouse and entered the Northern Canal.

Monitoring Station 29: Station 29 consisted of a single Lotek SRX radio-receiver and aerial antenna installed and calibrated to provide detection information for radio-tagged eels that passed through the Pawtucket Gatehouse, entered the E.L. Field Powerhouse forebay (i.e., the Northern Canal) and were in the vicinity of the entrance to the downstream bypass and intake racks.

Monitoring Station 31: This station consisted of a single Orion radio-receiver and underwater drop antenna installed and calibrated to provide detection information for radio-tagged eels exiting the forebay via the downstream bypass.

Monitoring Station 33: Station 33 consisted of a single Lotek SRX radio-receiver and aerial antenna installed to monitor across the bypassed reach at a point downstream of where the surge gate enters from the power canal and upstream of the downstream bypass discharge. Detections at this location were used to confirm the downstream passage of individuals using the spillway or surge gate.

Monitoring Station 35: This station consisted of a single Lotek SRX radio-receiver and aerial antenna installed at a location overlooking the E.L. Field Powerhouse tailrace. Detections at this location were used to confirm downstream passage of individuals via the Project turbine units.

Monitoring Station 37: This station was installed at a point along the mainstem of the Merrimack River downstream of both the E.L. Field Powerhouse tailrace and the confluence with the Concord River. Station 37 consisted of a single Lotek SRX receiver and aerial antenna oriented perpendicular to the river channel. Station 37 was installed at the Lowell Waste Water Treatment Plant, approximately 2.1 miles downstream of the tailrace.

Monitoring Station 39: Station 39 was installed at a commercial business near the midpoint between the Lowell and Lawrence projects and consisted of a single Lotek SRX receiver and aerial antenna oriented perpendicular to the river channel. Station 39 was located approximately 6.0 miles downstream of the tailrace.

Monitoring Station 40: This station consisted of a single Lotek SRX radio-receiver and an aerial antenna and was installed and calibrated in a manner to provide detection information for radio-tagged eels as they approached the upstream face of Essex Dam (approximately 10.75 miles downstream of the Lowell tailrace).

Monitoring Station 23: This station was installed to detect eels which entered the downtown canal system via the Pawtucket Canal rather than pass the Project via one of the mainstem passage routes. The entrance to the Pawtucket Canal sits at a point upstream of the Pawtucket Dam and the Northern Canal. Station 23 was installed at the Guard Locks, approximately 1,700 feet downstream from the entrance to the canal. The monitoring zone for Station 23 was directed downstream to ensure detections recorded at that location were of individuals which had definitively entered the downtown canal system.

4.3 Tagging and Release Procedures

Silver-phase American eels were purchased from a commercial eel trapper operating on the St. Croix River in Maine. Eels were transported by truck from the St. Croix area to holding tanks installed at Garvins Falls Dam (Merrimack River Project, Bow, NH) on October 3, 2019. The total number of eels available for purchase from the St. Croix River was slightly less than the number required to achieve the study sample size described in the FERC-approved RSP. An additional twelve silver eels were provided by the New Hampshire Fish and Game Department (NHFGD) following their collection in a sampling weir being operated on the Soucook River. NHFGD staff maintained Soucook River eels at the Nashua Fish Hatchery until Normandeau staff transported them to the holding tanks at Garvins Falls on October 21.

All eels were held for a minimum of 24 hours prior to tagging. Individuals were visually examined and if they appeared healthy were anesthetized in a clove oil and ethanol solution (Figure 4-4). Eels were held and visually monitored in the anesthesia bath for approximately 10–15 min prior to tagging. Once sedated, eels were removed from the bath and placed on a clean, wet towel. The total length (TL) and eye diameter (horizontal and vertical; nearest 0.1 mm) were measured. Although the capture method virtually guarantees sample specimens are migratory, a previously described correlation between eye size, body length and gonad development was used to confirm whether individuals were mature and likely to be active outmigrants (Pankhurst 1982). This eye index relationship (I) was described using the formula:

$$I = [(A+B/4)2\pi/L]*100$$

where A = horizontal eye diameter, B = vertical eye diameter, and L = total body length. Silver-phase American eels typically have an eye index between 6.0 and 13.5, with a bronze coloration along the lateral line that separates the dark, silver back from the white belly. Eels meeting

these characteristics were selected for surgical tagging. In short, an incision was made off center on the ventral surface of the individual and of an adequate length to insert the transmitter into the body cavity. A hollow needle was inserted into the incision and was pushed through the body wall just off of the ventral mid-line and at a point posterior to the incision. The antenna was fed through the needle and gently pulled so that the transmitter entered the body cavity. The needle was then fully pulled through the body wall and removed from the antenna. The transmitter was positioned by pulling the antenna so that it lay directly under the incision. The incision was closed with two or three interrupted sutures (chromic gut with a 4-0 cutting needle) evenly spaced across the incision. A small amount of an antibacterial ointment was applied to the incision site to prevent infection.

Following tagging, each individual was transferred to an acclimation tank supplied with ambient river water for an additional 24-h observation period to allow eels to recover from surgery. Following the recovery period, eels were assessed for normal behavior prior to release and were then trucked to the car-top boat launch located adjacent to the Northeast Delta Dental Stadium in Manchester, NH and upstream of the Lowell Project impoundment[1]. Radio-tagged individuals were carefully netted from the truck tank and were released from the shoreline. A total of five separate release groups, each comprising 20 radio-tagged eels were released during the 2019 study. The date and time of each release was recorded.

4.4 Data Collection

4.4.1 Stationary Telemetry Data

Receiver downloads occurred three to four times weekly during the period from the initial tag and release event until the end of November, 2019. Backup copies of all telemetry data were made prior to receiver initialization. Field tests at the time of download to ensure data integrity and receiver performance included confirmation of file integrity, confirmation that the last record was consistent with the downloaded data (beacon tags were critical to this step), and lastly, confirmation that the receiver was operational upon restart and actively collecting data post download. Within a data file, transmitter detections were stored as a single event (i.e., single data line). Each event included the date and time of detection, frequency, ID code, and signal strength.

4.4.2 Manual Telemetry Data

To provide supplemental detection information to the stationary receiver data set, manual tracking was conducted on a number of occasions from the time of initial release through the end of November, 2019. Manual effort was exerted in the vicinity of the Lowell Project (i.e., tailrace and headpond immediately upstream of Pawtucket Dam) on most dates when stationary telemetry equipment was checked. In addition, a number of boat or truck-based

[1] Normandeau Associates simultaneously conducted an additional downstream adult eel passage study at the Merrimack River Project (FERC No. 1893) during fall 2019. A total of 60 eels were radio-tagged during that assessment and were also monitored for passage at Lowell. Results from that group of eels at Lowell and points downriver have been incorporated into this report.

efforts were conducted to look for radio-tagged eels within the Lowell impoundment and the reach of the Merrimack downstream to Lawrence.

4.4.3 Operational and Environmental Data

Merrimack River water temperature was recorded via a continuously operating logger installed within the Lowell intake canal. Hourly records for operations data were provided by Boott for the 2019 evaluation period and included:

- Headpond elevation (ft);
- Power canal elevation (ft);
- Headpond-power canal differential (ft);
- Tailrace elevation (ft);
- Head differential for E.L. Field turbines (ft);
- Total inflow (cfs);
- Unit 1 discharge (cfs) and output (KW);
- Unit 2 discharge (cfs) and output (KW);
- Downstream bypass discharge (cfs);
- Upstream fishway discharge (cfs);
- Downtown canal flow (cfs); and
- Spill flow through the bypassed reach.

4.4.4 Downstream Drift Assessment

A total of ten freshly dead adult silver-phase eels were radio-tagged and released downstream of Lowell during the 2019 study period. Two individuals were released on each date that a group of live test eels was released upstream of the Lowell impoundment. Dead, radio-tagged eels were released directly into the discharge of an active turbine unit at the E.L. Field powerhouse. The downstream progression of these known mortalities was recorded via both the stationary receivers as well as during manual tracking events.

4.5 Data Analysis

The tagging, telemetry and Project operations data sets collected as part of this effort were examined and used to evaluate a number of metrics related to downstream passage success and movement through the Project area.

4.5.1 Downstream Movement and Passage Route Selection

A complete record of all valid stationary receiver detections for each radio-tagged adult American eel was generated. The pattern and timing of detections in these individual records were reviewed, and a route of passage as well as project arrival and passage times were assigned to each radio-tagged individual. In the instance that a downstream route could not be clearly determined from the collected data, the passage event for that particular fish was classified as ‘unknown’.

Where data were available, impoundment duration and project residence times were calculated. Values for impoundment duration were calculated as the duration of time from detection at Station 19 until detection at Station 21. Upstream project residence time was defined as the duration of time from the initial detection at Station 21 until the determined time of downstream passage. Time spent immediately upstream of the dam was further evaluated using initial detection times for eels at Monitoring Stations 25 and 27 to provide an understanding of passage times associated with moving through the Pawtucket Gatehouse and entering into the Northern Canal approach to the E.L. Field powerhouse.

4.5.2 Parameter Estimates for Evaluation of Downstream Passage

Downstream passage success at the Project was estimated for adult American eels using a standard Cormack-Jolly-Seber (CJS) model run for the set of individual encounter histories (i.e., the series of detection/no detection through the linear sequence of receivers from upstream to downstream; Lebreton et al. 1992). This approach provided a series of reach-specific "survival" or passage success estimates for:

- Monitoring Station 19 to Monitoring Station 21 (i.e., impoundment duration);
- Monitoring Station 21 (i.e., upstream approach) to downstream passage;
- Downstream passage to Monitoring Station 37 (i.e., first downstream receiver); and
- Monitoring Station 37 (i.e., first downstream receiver) to Monitoring Station 39 (i.e., second downstream receiver)

Standard error and confidence bounds for each estimate were generated. The joint probability of three reach survival estimates (i.e., (Lowell to Station 37)*(Station 37 to Station 39)*(Station 39 to Lawrence)) was used as the estimate of total passage survival for the Project. This approach resulted in a mortality estimate that included both background mortality (i.e., natural mortality such as predation) and mortality due to Project effects in the reach extending from Lowell downstream to Lawrence. Thus, the results presented in this report reflect a minimum estimate of survival attributable to Project effects for adult silver eels.

To evaluate passage success using the CJS models, a suite of candidate models were developed in Program MARK (White and Burnham 1999) based on whether survival (i.e., passage success), recapture (i.e., detection), or both vary or are constant among stations. Models developed during this study included:

- *Phi(t)p(t)*: survival and recapture may vary between receiver stations;
- *Phi(t)p(.)*: survival may vary between stations; recapture is constant between stations;
- *Phi(.)p(t)*: survival is constant between stations; recapture may vary between stations;
- *Phi(.)p(.)*: survival and recapture are constant between stations;

Where;

- *Phi* = probability of survival
- *p* = probability of detection
- *(t)* = parameter varies
- *(.)* = parameter is constant

To evaluate the fit of the CJS model, goodness of fit testing was conducted for the "starting model" (i.e., the fully parameterized model) using the function RELEASE within Program MARK. Akaike's Information Criterion (AIC) was used to rank the models as to how well they fit the observed mark-recapture data (Lebreton et al. 1992). Lower AIC values denote a more explanatory yet parsimonious fit than higher AIC values. Assuming the assumptions of the model with the lowest AIC value were reasonable with regards to this study, that model was selected for the purposes of generating passage effectiveness estimates.

Models were prepared which evaluated downstream passage success of adult eels at Lowell as follows:

- All eels – based on detection at Station 37, Station 39 and Lawrence;
- Garvins Falls release group – based on detection at Station 37, Station 39, and Lawrence;
- Lowell Project release group – based on detection at Station 37, Station 39, and Lawrence;
- All eels – adjusted for median "travel time" for freshly dead eels released in Lowell tailrace to reach Lawrence (i.e., test eels with downstream travel times in excess of median drift duration manually adjusted to reflect a mortality at the Project); and
- All eels – by downstream passage route.

4.5.3 Time to Event Analysis

4.5.3.1 Cox Proportional Hazard Model

Utilizing available methodology for quantifying fish passage performance (Castro-Santos and Perry 2012), multi-variate Cox proportional hazard models were developed to assess the impact of various operational and environmental variables on the rate of passage success. Operational and environmental variables considered as part of this analysis included:

- Merrimack River water temperature (^{o}C);
- Head differential (ft) at the Pawtucket Gatehouse (i.e., headpond vs. Northern Canal);
- Bypassed reach spill flow (cfs);
- E.L. Field turbine discharge (cfs);
- Merrimack River inflow (cfs); and
- E.L. Field head differential (ft) (i.e., Northern Canal vs. tailwater).

This assessment on the rate of passage success focused on approach events at (1) the Pawtucket Gatehouse (i.e., Station 25), and (2) at the E.L. Field Powerhouse (i.e., Station 29).

Regression models for the time to event analyses were constructed using the *coxph*() function from the package "*survival*" in R (R Core Team 2020) and were used to evaluate the rate of passage success and identify operational hazards at sites which contained a physical barrier or a structure through which tagged individuals would have to navigate (i.e., the Pawtucket Gatehouse and E.L. Field Powerhouse).

The Cox proportional hazard regression can be described as a hazard function to evaluate the proportionate risk at time (t) such that

$$h(t) = h_0(t) \times exp(b_1x_1 + b_2x_2 + \ldots + b_ix_i)$$

where $h(t)$ represents that hazard at a given time point which is equal to the initial or baseline hazard at time 0:00 ($h_0(t)$) multiplied by e (the base of the natural logarithm) to the power of the additive relationship between each covariate (x_i) multiplied by its associated coefficient (b_i).

From the above equation, the relative impact of an operational parameter on the rate of passage success is represented by its associated coefficient. The hazard ratio of a given operational parameter is calculated by exponentiating the coefficient of a given parameter, which represents that multiplicative impact of that parameter. It is important to note that exponentiating these coefficients makes the value relative to a value of 1 (e^0), which represents a baseline of no hazard. For example, if the hazard ratio is greater than 1, e.g., 1.5, that will be interpreted as that covariate increasing the risk of passage failure by a factor of 1.5. Alternatively stated, a hazard ratio of 1.5 indicates that the associated covariate increases the risk by 50% as it is 0.5 greater than 1. In contrast, a hazard ratio below 1, e.g., 0.75, indicates that the associated covariate reduces the risk of passage failure by a factor of 0.75, or 25%. In short, a hazard ratio >1 indicates an increase in the risk of passage failure, a hazard ratio of 1 indicates no significant directional effect on passage, and a hazard ratio <1 indicates a reduction in the risk of passage failure.

4.5.3.2 Model Evaluation and Selection

As is the case with any statistical model, the type of model selected makes inherent assumptions about the nature of the data being modelled. The primary assumption of a Cox proportional hazard model is that the hazards are proportional. However, this assumption is not always appropriate for the data. As a result, the *cox.zph()* function was used during this assessment to assess the validity of the proportional hazard assumption. This function assessed scaled Schoenfield residuals to evaluate whether Cox regression residuals of each covariate in addition to the model as a whole are independent of time. In the event that the Schoenfield residuals are not independent of time, it can be said that the assumption of proportional hazards is violated and a Cox proportional hazards model may be misrepresentative of the true relationships between the selected covariates and passage success.

4.5.3.3 Event Definition

To evaluate the impact of operational parameters on passage success, instances of passage success and failure required definition and represent the 'events' (or passage attempts) in this analysis. Ostensibly, the transmitters deployed during this study should transmit a signal that when within range of a particular receiver will be detected every 2.0 seconds. However, various sources of outside noise or areas of poor coverage due to structures, etc. introduce variation into the frequency of detection for a unique transmitters signals. Given that different site locations and receiver types are subject to varying degrees of ambient noise, the duration between successive detections was calculated for each tagged individual at each receiver location. A threshold interval for determining continued presence of a transmitter within the detection zone of a specific receiver was identified as the 95th percentile of the observed set of interval durations. This value was calculated at 14.4 seconds for Station 25 and 32.4 seconds for Station 29. These two threshold values were then used to delineate when each event was started and completed for a tagged individual. The departure of a radio-tagged individual from the detection zone of a particular receiver was determined when the time interval between successive detections exceeded the specific threshold interval for that zone.

From this, a passage failure event (assigned a value of 0) was defined as any duration where all detections lay within the 95th percentile of durations for all individuals at that site. Passage failure represents events in which a tagged individual enters the field of detection at a given site without passing to the next site (i.e., moving downstream) in the system. A passage success event (assigned a status of 1) was defined using the final instance of detection for a tagged individual at a singular site where that tagged individual was next detected at a downstream receiver (i.e., successfully passed). Passage success/failure (1/0) was used as the status coinciding with time in the Cox proportional hazard models. After defining passage events for every individual, the time duration for the regression was defined as the duration from one event to the next.

5 Results

5.1 Merrimack River Conditions and Lowell Project Operations

Figure 5-1 presents the Merrimack River flow and water temperature for the period of time from the first eel release on October 9 until the end of the monitoring period on November 31, 2019. Water temperatures at Lowell ranged from 16°C at the onset of the study to 2°C on November 30. Total river flow values represent the reported inflow at the Lowell Project. Merrimack River flow at Lowell ranged between 1,089 and 12,995 cfs during the nearly two month fall study period. Figure 5-2 presents the monthly flow duration curves prepared for Lowell during the development of the Preliminary Application Document. The median flow condition at the Project is approximately 3,600 cfs during October and 6,500 cfs during November. Merrimack River conditions have a ~20% probability during October and a ~38% probability during November to exceed the ~8,000 cfs capacity of the E.L. Field powerhouse.

Table 5-1 summarizes the percentage of inflow records from the 2019 study period categorized by volume (to the nearest 1,000 cfs) as well as the percentage of time that each volume category is historically exceeded[2]. To help characterize the 2019 passage season, monthly exceedance probabilities less than 0.35 were classified as "high" flow conditions, 0.35 to 0.65 were classified as "normal" flow conditions, and greater than 0.65 were classified as "low" flow conditions. Inflows at the Project for the period October 9 through 31 were representative of high flow conditions (i.e., those with a probability of exceedance of less than 0.35) for 35% of the period, normal flow conditions (i.e., those with a probability of exceedance of 0.35-0.65) for 29% of the time and low flow conditions (i.e., those with a probability of exceedance of greater than 0.65) for 36% of the time. For the month of November, inflows were representative of high flow conditions 26% of the time, normal flow conditions 15% of the time and low flow conditions 59% of the time.

Flow duration information for the months of October and November (combined) is presented in Figure 5-3. The median flow condition during the two month period is near 5,000 cfs. When characterized using the flow condition criteria above, inflows at the Project for the period October 9 through November 30 were representative of high flow conditions (i.e., those with a probability of exceedance of less than 0.35) for 19% of the period, normal flow conditions (i.e., those with a probability of exceedance of 0.35-0.65) for 56% of the time and low flow conditions (i.e., those with a probability of exceedance of greater than 0.65) for 24% of the time (Table 5-1).

Figure 5-4 summarizes the allocation of water among the E.L. Field powerhouse, bypassed reach, downstream fishway, and downtown canal system at Lowell. Turbine units were in operation at the E.L. Field powerhouse for the duration of the study period with Unit 1 in operation throughout the study and Unit 2 coming online at 0900 on October 16. The

[2] Estimates of monthly exceedance estimated from monthly flow duration curves provided in Appendix H of the PAD.

downstream bypass was operated throughout the study period, passing approximately 132 cfs (i.e., 2% of the nameplate capacity of the E.L. Field turbine units; 6,600 cfs). Two major spill events, associated with increases in river flows, occurred during the monitoring period. The first major spill event occurred from approximately October 29 to November 5 and the second occurred towards the end of the passage season (~November 25). Flows to the downstream canal system represented between 15-20% of the 2,000 cfs capacity during October and between 20-57% of the 2,000 cfs capacity during November. Due to overriding safety concerns, Boott limited operation of the turbine units within the downtown canal system during the study period. To the extent possible, Boott's operations staff attempted to operate the canal system as if there were canal units available, by opening gates when river flows exceeded the hydraulic capacity of the E.L. Field turbines (7,000 to 8,000 cfs). As a result, flows through the downtown canal system were largely restricted to passage via open gates. The Licensee manually recorded gate and unit settings during the study period within the downtown canal system. A breakdown of those values and related discharge estimates are provided in Appendix A.

Table 5–1. Frequency of occurrence of river inflow at Lowell (to nearest 1,000 cfs) during 2019 adult American eel passage assessment and corresponding percentage of time flows are historically exceeded.

River Flow (nearest 1k)	October 9-30, 2019		November 1-30, 2019		Oct 9 - Nov 30, 2019	
	Percentage of Month	Percentage of Month Historically Exceeded	Percentage of Month	Percentage of Month Historically Exceeded	Percentage of Period	Percentage of Period Historically Exceeded
1000	16.1%	90	-	> 95	7.0%	>95
2000	19.4%	85	-	> 95	8.4%	90

5.2 Monitoring Station Functionality

Radio-tagged adult American eels were released into the Merrimack River beginning in early October, 2019. The RSP called for continuous monitoring at each stationary receiver location through the end of November. Figure 5-5 provides an overview of the continuity of monitoring at each of the twelve stationary receiver locations during the fall period. The majority of the radio-telemetry monitoring stations installed to evaluate passage at Lowell during the fall study operated without issue for the full period.

Interruptions in continuous coverage were observed at three locations during the latter part of the study when lessened levels of daylight led to reduced efficiency of solar panel charge. These locations included Station 19 (upstream end of the Lowell impoundment) from 2000 on November 10 to 1400 on November 12, Station 27 (downstream side of the Pawtucket Gatehouse) from 0830 to 1030 on November 12, and Station 37 (first receiver downstream of Lowell) from 0200 to 1300 on November 5. Potential impacts to the study results from these three outages were likely limited. A single radio-tagged eel which approached the Pawtucket Dam after 2000 on November 10 lacked a detection at Station 19 and may have passed during the outage at that location preventing calculation of an impoundment residence duration for that individual. The outage at Station 27 was extremely short in duration and there were no radio-tagged eels detected upstream of the gatehouse that went undetected at that location prior to initial detection in the E.L. Field forebay. No radio-tagged eels passing downstream of Lowell on November 5 (or preceding two dates) went undetected at Station 37.

The aerial antenna at Station 25 (upstream side of the Pawtucket Gatehouse was removed by Boott operations staff to facilitate the installation of a crane to remove the in-river debris load from the upstream side of the gatehouse structure on November 21. A single radio-tagged eel did approach on November 22 and the outage at that station prevented a determination of the time to pass through the Pawtucket Gatehouse for that individual.

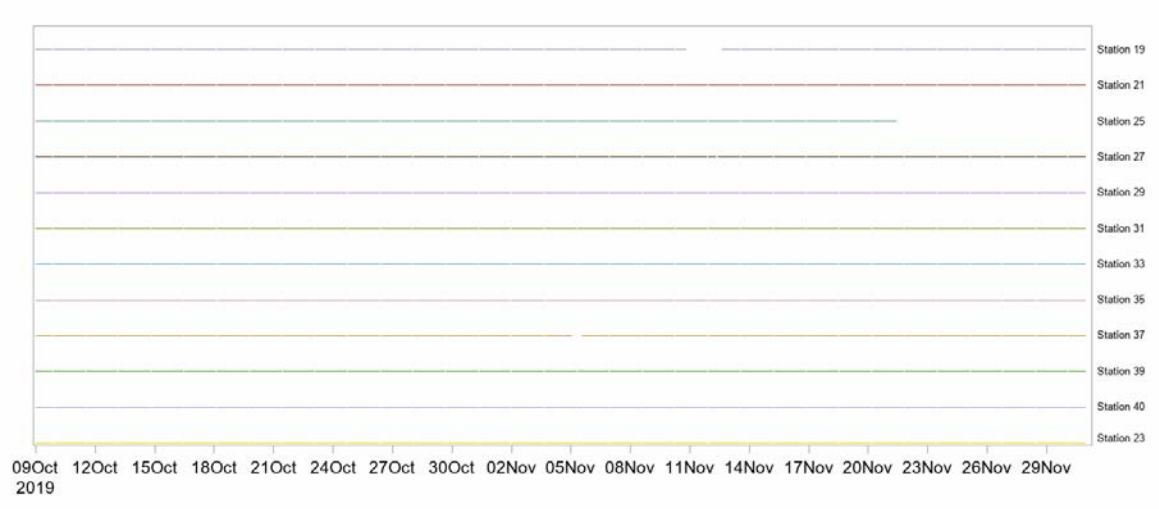

Figure 5–5. Operational coverage for telemetry receivers at Lowell during the adult silver eel downstream passage assessment, October 9 to November 30, 2019.

5.3 Downstream Drift Assessment

A total of ten freshly dead, radio-tagged American eels were released from the back deck of the E.L. Field powerhouse and directly into the upper portion of the discharge from an active turbine unit during the 2019 evaluation period. Freshly-dead eels were released intact and would be representative of an individual which did not suffer a physical strike which may result in partial or full severing of the body. Two individuals were released in the tailrace on each date where a group of radio-tagged eels were released upstream of the Project impoundment in Manchester, NH. Table 5-2 provides a summary of the release schedule and date-time of first detection for the drift eels to arrive at monitoring stations downstream of Lowell (Stations 37, 39, and 40).

Of the ten freshly dead, radio-tagged eels released at Lowell, seven were eventually detected at Station 40 (located at Lawrence, 10.75 miles downstream of the Lowell tailrace). The median duration to drift from the Lowell tailrace downstream to Lawrence was 216.4 hours (range = 59.4-538.9 hours). Three freshly dead eels did not drift the full distance from the tailrace to Station 40 at Lawrence. Of those individuals, two moved away from the Lowell tailrace but were not detected at Station 37 (2.1 miles downstream of Lowell). The third individual drifted from the Lowell tailrace to Station 37 over a period of 247.8 hours.

5.4 Eel Tagging and Releases

Eels were tagged and released upstream of the Project starting on October 9 and ending on October 23. Monitoring coverage at Lowell provided detection information on radio-tagged individuals released upstream of Lowell as part of this relicensing study (n = 102) as well as individuals released as part of a separate study conducted upstream at Garvins Falls Dam (Merrimack River Project, FERC No. 1893; n = 60) in Bow, NH. Table 5-3 provides a summary of the release dates and number of individuals for the 2019 passage assessment. A total of 162 live, radio-tagged adult eels were released over a span of two weeks and were potentially available for evaluation of downstream passage at Lowell. The majority of those individuals originated from the St. Croix River whereas the rest were captured locally (Soucook River; n = 10).[3] Eels tagged and released at locations upstream of Lowell as part of the 2019 passage evaluation ranged in length from 646 to 1,032 mm with the highest contribution of individuals to the 800-849 mm length class (Figure 5-6). The mean length of radio-tagged individuals released upstream of Garvins Falls (mean = 828 mm; range = 646-999 mm) was similar to that for eels released upstream of the Lowell impoundment (mean = 823 mm; range = 679-1,032 mm). The majority of eye index values recorded (98%) were within the literature reported range (6.0-13.5) for outmigrating eels. A full listing of tagging and biocharacteristics information for eels released during 2019 is provided in Appendix B.

[3] See Appendix D for a comparison of passage metrics for the October 23 release group comprised of eels originating from the Soucook River (n = 10) and St. Croix River (n = 12).

5.5 Impoundment Passage

Radio-tagged eels released upstream of the Lowell impoundment and upstream of Garvins Falls Dam were initially detected at Monitoring Station 19, located at the upstream extent of the Lowell impoundment (~ 23 miles from the Pawtucket Dam). The duration of time for radio-tagged individuals to move through the Lowell impoundment and arrive at the Pawtucket Dam (as indicated by detection at Station 21) ranged from 12.5 hours to 16.4 days (Table 5-4; Figure 5-7. The median duration of time spent in the Lowell impoundment was 2.1 days and did not appear to differ for eels originally released upstream of the Lowell impoundment or upstream of Garvins Falls.

5.6 Project Arrival and Upstream Residence Duration

Releases of radio-tagged eels were initiated on October 9 at locations upstream of the Project boundary and upstream of Garvins Falls Dam. Figure 5-8 presents the distribution of arrival dates for radio-tagged eels at the Pawtucket Dam as indicated by detection at Station 21. Initial detections for eels were recorded over a range of dates from October 13 through November 22 with just over fifty percent of individuals initially detected between the dates of October 24 and 30.

The duration of time radio-tagged individuals were present upstream of the Pawtucket Dam was determined for all individuals which approached and eventually passed downstream and was calculated as the duration of time from initial detection at Station 21 until confirmed downstream passage via one of the available routes. When all individuals are considered, upstream residence duration prior to downstream passage ranged between 0.2 hours to 16.5 days (Table 5-5; Figure 5-9). The median duration of time spent immediately upstream of the dam structure was 0.4 hours and did not appear to differ for eels originally released upstream of the Lowell impoundment or upstream of Garvins Falls. Of the radio-tagged eels which approached Pawtucket Dam, 94% passed in fewer than 24 hours after initial detection. Eight radio-tagged adult eels took greater than 24 hours to pass downstream following their initial detection at Station 21.

Outmigrating adult eels encountering the Pawtucket Dam can (1) pass through the Pawtucket Gatehouse and enter the power canal, (2) pass downstream over Pawtucket Dam via spill, or (3) enter the Pawtucket Canal and navigate downstream via the downtown canal system. During the 2019 evaluation there were no detections of radio-tagged eels at Monitoring Station 23 indicating individuals passed downstream of Lowell in the mainstem Merrimack rather than entering the downtown canal system. The majority of radio-tagged eels were determined to have passed through the Pawtucket Gatehouse and entered the Northern Canal to approach the E.L. Field powerhouse. The duration of time to pass through the Pawtucket Gatehouse was determined based on the initial detection for each individual eel at Stations 25 and 27 which independently monitored the upstream and downstream sides of that structure. The median duration of time for radio-tagged eels to approach and pass through the Pawtucket Gatehouse was 0.1 hours (range <0.1 hours to 3.9 days; Table 5-6). The vast majority (95%) of radio-tagged eels passing through the Pawtucket Gatehouse did so in 30 minutes or less.

Similar to observations at the Pawtucket Gatehouse, radio-tagged eels which entered the Northern Canal and passed downstream of E.L. Field powerhouse did so relatively quickly. Of those individuals, 94% were resident in the power canal upstream of E.L. Field for 3 hours or less. The median residence duration in the Northern Canal was 0.2 hours (range = 0.1 hours to 22.1 days; Table 5-7). Seven radio-tagged individuals were present in the Northern Canal for 36 hours or greater prior to downstream passage.

5.7 Downstream Passage

A total of 162 radio-tagged eels were released at points upstream of the Lowell Project during the fall of 2019. Of that total, 147 were determined to have approached the Pawtucket Dam and were available for the evaluation of downstream passage route (Table 5-8). The majority of radio-tagged individuals passed through the Pawtucket Gatehouse and approached the E.L. Field powerhouse. Most individuals (92.5%) passed downstream of Lowell via the E.L. Field turbine units. Use of the downstream bypass was limited to two individuals (1.4% of those approaching the Pawtucket Dam). Use of the bypassed reach was limited to four individuals, representing 2.8% of radio-tagged eels which approached the Pawtucket Dam.

Radio-tagged silver eels were observed passing downstream of Lowell between the dates of October 13 and November 22 (Figure 5-10). Downstream passage of radio-tagged eels at Lowell peaked during the last part of October with 81% of all downstream passage events at the Project occurring on or before October 31. Figure 5-11 presents the timing distribution of downstream passage events for silver eels at Lowell. The majority of individuals passed downstream at dusk (hours 1800 – 2200) with a peak in the number of downstream passage events during the hour of 2000 (20%).

For each of the 142 individuals which were confirmed to have passed downstream of Lowell via a known passage route (i.e., turbine, downstream bypass, or spill) the hourly record of Project operations (Section 5.1) at the time of passage was reviewed. The discharge at the selected route was identified and contrasted with the cumulative discharge for all non-selected routes at the time of downstream passage (Table 5-9). The majority of radio-tagged eels passing downstream at Lowell did so via the E.L. Field turbine units. The median discharge through the two E.L. Field turbine units at the time of passage for those individuals was 4,122 cfs. When examined by passage route, the median percentage of passage route flow at each known downstream passage route represented 78% of project flow for turbine passed eels, 2% of project flow for downstream bypass passed eels and 41% of project flow for spill passed eels. Passage via the downstream route with the greatest proportion of flow at the time of passage occurred 87% of the time. A listing of route discharge at the time of downstream passage for each eel is provided in Appendix F.

5.8 Downstream Transit

Three monitoring stations were installed downstream of Lowell for the purpose of detecting radio-tagged adult eels following passage at the Project. Those receivers were located approximately 2.1 (Monitoring Station 37), 6.0 (Monitoring Station 39), and 10.75 (Monitoring

Station 40) miles downstream of the project. The minimum, maximum, and quartile transit times through those three reaches are presented in Table 5-10. The median transit time durations for tagged adult eels moving downstream of Lowell were 2.1, 15.0, and 21.8 hours for the 2.1 mile, 3.9 mile and 4.75 mile-long downstream reaches, respectively.

Table 5-11 and Figure 5-12 present the minimum, maximum and quartile transit times for radio-tagged silver eels to cover the reach from immediately downstream of Lowell to the upstream face of the Essex Dam in Lawrence (i.e., Station 40). The median travel time for radio-tagged eels to approach Lawrence following downstream passage at Lowell was 2.3 days (range = 6.7 hours to 38.2 days). Figure 5-13 presents the distribution of observed downstream transit rates for radio-tagged eels moving from Lowell to Lawrence. Reference lines for the 25, 50, and 75% quartiles observed for the freshly-dead drift eels are included (5.7, 9.0, and 19.0 days, respectively; Table 5-2). Of the live-radio-tagged eels which passed downstream of Lowell and were subsequently detected at Lawrence, 85% did so in less time than the 25th percentile of occurrence for the dead drift eels, 91% did so in less time than the 50th percentile (median) of occurrence for the dead drift eels, and 99% did so in less time than the 75th percentile of occurrence for the dead drift eels.

5.9 Passage Survival

The CJS model *Phi(t)p(t)* provided the best fit for the observed mark-recapture data associated with downstream movements of radio-tagged silver-phase American eels approaching and passing at Lowell during 2019 (Table 5-12). The detection efficiency for telemetry receivers recording passage of adult eels at monitoring stations at Lowell and Lawrence as well as the remote riverside locations ranged from 1.000 to 0.839 (Table 5-13). The relatively poor detection efficiency rate (0.839) was estimated for Station 37 (first receiver downstream of Lowell). It is suspected that background interference in the vicinity of the Waste Water Treatment Plant property may have led to the lower than desired detection rate. However, detection was 100% for eels at Station 39 and Lawrence.

The reach-specific survival estimates for the Merrimack River from the upstream extent of the Lowell impoundment to detection immediately upstream of Lawrence are presented in Table 5-14. There was no mortality associated with passage for adult radio-tagged eels moving downstream through the Lowell impoundment. Passage success for downstream adult American eels at Lowell was calculated as the joint probability of the three reach-specific survival estimates which encompasses the full section of the Merrimack River from Lowell downstream to Lawrence (i.e., Lowell to Station 37, Station 37 to Station 39, and Station 39 to Lawrence). This resulted in an estimated downstream passage survival for silver-phase American eels at Lowell of 75.5% (75% CI = 71.4%-79.6%). Estimates of downstream passage for eels released upstream of Garvins Falls (75.6%; 75% CI = 68.8%-82.2%) and immediately upstream of the Lowell impoundment (75.5%; 75% CI = 70.5%-80.4%) did not differ.

Encounter histories for all radio-tagged eels which approached and passed downstream of Lowell were evaluated relative to the calculated downstream transit durations for freshly dead eels released into the Lowell tailrace. Individual test eels with a transit duration from Lowell to

Lawrence in excess of the median duration required to drift the 10.75 mile reach were manually adjusted to reflect mortality at the Lowell Project. When those individuals are adjusted, the estimate of overall project passage survival at Lowell is 68.7% (75% CI = 64.5%-72.9%).

Radio-tagged eels which approached and passed downstream at Lowell during the 2019 evaluation did so primarily via the E.L. Field turbine units (Table 5-8) and the number of individuals (n = 136) permitted the generation of a route-specific passage survival rate (75.0%; 75% CI = 70.6%-79.4%). The limited number of radio-tagged eels passing the Project via spill (n = 4) or via the downstream bypass system (n = 2) were all determined to have successfully approached the Lawrence Project following downstream passage at Lowell.

5.10 Time to Event Analysis

A total of 144 Pawtucket Gatehouse and 61 E.L. Field Powerhouse forebay events were defined based on recorded detections of adult American eels during the 2019 study to evaluate the impact of operational parameters on passage success. The median event duration recorded for a radio-tagged adult eel was 1.6 minutes for individuals in the detection field of Station 25 immediately upstream of the Pawtucket Gatehouse and 29 seconds for individuals in the detection field of Station 29 covering the area immediately upstream of the intakes to the downstream bypass and turbine units at the E.L. Field Powerhouse.

5.10.1 Pawtucket Gatehouse

Results of the Cox proportional hazard model for the Pawtucket Gatehouse can be found in Table 5-15 and illustrated in Figure 5-14. Model results suggest a statistically significant and negative relationship between water temperature and passage success at the Pawtucket Gatehouse wherein a decrease in temperature leads to a 22% increase in the probability of passage failure (i.e., the probability of successfully passing downstream through the Pawtucket Gatehouse decreases as the water temperature decreases (presumably later in the season)). For this model, inflow data was split into three bins based on volume: 1080-5060 cfs (i.e., low), 5060-9030 cfs (i.e., mid), and 9030-13,000 cfs (i.e., high). The low inflow condition was used as a reference for comparison with mid and high inflow conditions, as illustrated in Figure 5-14. Although the model suggests an insignificant, negative relationship between inflow values from 1080-5060 cfs and passage success, a statistically significant, positive relationship was found between passage success and high inflow values ranging from 9030-13,000 cfs. This indicates inflow values classified as “high” reduced the probability of passage failure by 33% (i.e., likelihood of successful passage at the Pawtucket Gatehouse increases with rising inflow). Similarly, spill data was split into three bins: 0-3040 cfs (i.e., low), 3040-6070 cfs (i.e., mid), and 6070-9120 cfs (i.e., high) and the low spill flow category was used as reference for comparison with mid and high spill conditions (Figure 5-14). Mid-levels of spill flow were found to be significantly correlated with passage success. The probability of passage failure for adult eels at the Pawtucket Gatehouse decreases by 79% when spill is between 2080 and 6070 cfs. Additionally, it should be noted that Table 5-16 demonstrates the Pawtucket Gatehouse model meets the criteria necessary to accept the assumption that hazards are proportional, as all covariates were found to be independent of time.

5.10.2 E.L. Field Powerhouse Forebay

Results of the Cox proportional hazards model for E.L. Field forebay events suggest a statistically significant, negative relationship between both water temperature and the forebay-tailrace head differential versus passage success, increasing the probability of passage failure by 26% and 58%, respectively (Table 5-17). In order to make sure the data met the assumption of proportional hazards and ensure the use of an appropriate modelling framework, spill was maintained as a continuous variable and inflow was split into three bins (1080-5060 cfs (i.e., low), 5060-9030 cfs (i.e., mid), and 9030-13,000 cfs (i.e., high; Table 5-17). However, neither spill nor inflow were found to be significant variables with neither exhibiting a measurable impact on passage success out of the E.L. Field Powerhouse forebay. Model results indicate the combined turbine discharge (cfs) exhibited a negative, statistically significant impact on passage success, which was also classified into three bins: 592-1980 cfs (i.e., low generation), 1980-3950 cfs (i.e., mid generation), and 3950-5930 cfs (i.e., high generation). As illustrated in Figure 5-15, the low generation category was used as a reference for comparison to the mid and high generation conditions. Results suggest a strong, statistically significant interaction for the rate of passage failure under the mid and high generation conditions with an increase in the observed rate of passage failure for those two conditions relative to the low generation condition. Table 5-18 demonstrates that the E.L. Field Powerhouse forebay model meets the criteria necessary to accept the assumption that hazards are proportional, as all covariates were found to be independent of time.

5.11 Manual Tracking

In addition to the continuous monitoring provided by the 12 stationary receivers installed throughout the Project area for the duration from early October through November 2019, a total of 116 manual detections representing 66 individuals were recorded between October 21 and November 25. Appendix C contains a listing of manual detections identified to the nearest 0.25 mile and classified as “Transit” for eels which were detected at stationary receivers downstream of their manually determined position or “Stationary” for eels which were not detected again at stationary receivers downstream of their manually determined position(s). A total of 39 individuals were located a single time within the Lowell impoundment with the majority (38 or 39) representing an individual which exhibited continued downstream movement following manual detection. A total of 10 individuals were manually detected within the Merrimack River downstream of Lowell and upstream of Station 37. The majority of those individuals (8 of 10) represented stationary individuals which were not detected at any of the downstream stationary receivers (i.e., Stations 37, 39, or 40). Similarly, a total of 18 individuals were manually detected within the Merrimack River between Stations 37 and 39. The majority of those individuals (11 of 18) represented stationary individuals which were not detected at additional downstream stationary receivers (i.e., Stations 39, or 40). Five radio-tagged eels were each detected on a single occasion in the reach between Station 39 and immediately upstream of Lawrence (Station 40).

Table 5–2. Summary of the downstream drift distance and duration for freshly dead, radio-tagged silver eels released in the Lowell tailrace during the downstream passage assessment, October 9 to November 30, 2019.

Release Date	River Condition (cfs)		Frequency (ID)	Total Length (mm)	Station 37 Arrival		Station 39 Arrival		Station 40 Arrival		Drift Duration

6 Summary

An evaluation of the potential impacts on the outmigration of adult silver-phase American eels was conducted in support of the FERC relicensing of the Lowell Project on the Merrimack River. Downstream passage effectiveness was evaluated using radio-telemetry during the 2019 fall migration season (October 9 to November 30, 2019). Monitoring of outmigrating adult American eels focused on the evaluation of movement through the Project impoundment, residence time immediately upstream of the Pawtucket Dam and prior to passage, passage route utilization and estimation of downstream passage survival at the Project.

A total of 102 adult silver eels were tagged and released at a shoreline location approximately 11 miles upstream of the upper end of the Lowell Project impoundment. Their subsequent downstream arrival and passage at the Project was monitored via a series of fixed-location telemetry receivers within the Lowell Project area. Arrival and downstream passage information was also monitored for 60 radio-tagged individuals released upstream of the Garvins Falls Dam as part of a separate study. The majority of individuals (152 of the 162) were obtained from a commercial vendor operating on the St. Croix River, Maine. The New Hampshire Fish and Game Department provided an additional 12 adult eels collected by a weir in the Soucook River, ten of which were also radio-tagged and released upstream of the Lowell impoundment. All 162 individuals were surgically radio-tagged and were released into the Merrimack over a range of release dates between October 9 and 23.

Radio-tagged eels moved through the 23 mile long Project impoundment in a median duration of 2.1 days. Upon initial detection at the Pawtucket Dam, the median duration of time spent immediately upstream of the dam structure was 0.4 hours with 94% passing downstream within the first 24 hours of their initial detection. Closer examination of the total residence time for radio-tagged eels indicated that the 95% of individuals passing through the Pawtucket Gatehouse did so in 30 minutes or less and upon entry into the Northern Canal the median residence duration prior to downstream passage was 0.2 hours.

Outmigrating adult eels encountering the Pawtucket Dam can (1) pass through the Pawtucket Gatehouse and enter the power canal, (2) pass downstream over Pawtucket Dam via spill, or (3) enter the Pawtucket Canal and navigate downstream via the downtown canal system. Individuals which enter the Northern Canal can pass downstream via one of the two turbine units at the E.L. Field Powerhouse, utilize the downstream bypass, or pass via the surge gate (operated only in the event of a station trip). During the 2019 evaluation there was no use of the downtown canal system. The majority of radio-tagged individuals passed through the Pawtucket Gatehouse and approached the E.L. Field powerhouse with 92.5% eventually passing downstream via the turbine units. Use of the existing downstream bypass system was limited to only two individuals. Downstream passage at the Project peaked during late October with all passage events completed by October 31. The majority of downstream passage events occurred during the evening and overnight hours.

Downstream passage survival was estimated for all radio-tagged eels from the point of initial detection upstream of the Pawtucket Dam downstream to Lawrence. This resulted in an

estimated downstream passage survival for silver-phase American eel at Lowell of 75.5% (75% CI = 71.4%-79.6%). This estimate of downstream passage survival for adult eels at the Project includes any background (i.e., natural) or tagging-related mortality for the species in the reach from approach to the Pawtucket Dam to Lawrence. As a result, this estimate should be viewed as a minimum estimate of total project survival (i.e., due solely to project effects) for adult eels at the Project. Due to the limited distribution of downstream passage route selection, route-specific estimates of passage were developed for only individuals using turbine units at the E.L. Field powerhouse (n = 136; 75.0% survival; 75% CI = 70.6%-79.4%). The limited number of radio-tagged eels passing the Project via spill or the downstream bypass system were all determined to have successfully approached the Lawrence Project following downstream passage at Lowell.

7 Variances from FERC-Approved Study Plan

The FERC-approved RSP indicated that a total of 100 radio-tagged silver-phase American eels would be released just upstream of upper boundary of the Project impoundment. The availability of two additional transmitters and test eels resulted in a total of 102 radio-tagged individuals released upstream of Lowell. To further enhance the sample size for evaluation of downstream passage, Boott also monitored the passage of radio-tagged silver-phase adult eels released further upstream in the Merrimack River. This resulted in an additional 45 individuals which approached Lowell and were available for analysis. There were no additional variances from the FERC-approved study plan.

Appendix C. Listing of manual tracking detections within the Lowell Project area.

River mile demarcations for reaches defined by stationary receivers:

Reach	River Mile	
	Upper End	Lower End
Station 19-Station 21	61.5	41.75
Station 35-Station 37	41.75	39.25
Station 37-Station 39	39.25	35.25
Station 39-Station 40	35.25	30.25

Date	Frequency	ID	RM	Location	Type
10/21/2019	149.340	74	42	Station 19-Station 21	Transit
10/28/2019	149.340	156	42	Station 19-Station 21	Transit

Appendix D. October 23, 2019 eel release: Soucook and St. Croix River eels.

The October 23, 2019 release of radio-tagged eels upstream of the Lowell impoundment was comprised of 10 individuals originating from the Soucook River in New Hampshire and 12 individuals originating from the St. Croix River, Maine. Table D-1 provides a comparison of the range of values for movement indices evaluated during this study and between the two groups. For most metrics the median duration did not appear to differ between the two groups. The median duration to pass downstream through the Lowell impoundment was nearly twice as long for eels originating in the St. Croix River. However, the minimum duration to do so was nearly the same for eels from both locations.

With regard to passage at Lowell there was no differentiation in passage route usage. All ten eels originating in the Soucook River and eleven of the twelve[8] eels originating in the St. Croix River passed downstream via the turbine units. Based on downriver detections, 83% of the eels originating in the St. Croix River and 80% of the eels originating in the Soucook River reached the Essex Dam in Lawrence.

Table D-1. Minimum, maximum, and quartile values for the suite of movement metrics assessed for radio-tagged eels originating from the Soucook and St. Croix Rivers and released upstream of the Lowell project boundary on October 23, 2019.

Movement Metric	Origin	Value				
		Min	Max	P25	Median	P75
Impoundment Duration (hrs)	Soucook	23.2	51.5	23.4	26.7	26.8
	St. Croix	25.4	71.8	29.0	49.9	66.0
Upstream Residence Duration (hrs)	Soucook	0.3	94.4	0.3	0.5	22.6
	St. Croix	0.2	165.3	0.3	0.4	1.5
Pawtucket Gatehouse Passage (hrs)	Soucook	<0.1	93.5	0.1	0.1	0.2
	St. Croix	<0.1	0.2	0.1	0.1	0.1
Northern Canal Residence (hrs)	Soucook	0.1	38.6	0.2	0.3	0.4
	St. Croix	0.1	165.1	0.2	0.2	0.3
Downstream Travel: Lowell to Lawrence (hrs)	Soucook	41.9	359.8	47.0	57.6	102.8
	St. Croix	21.1	196.7	26.1	60.9	97.6

[8] Passage route for one individual was left as unknown.

Appendix E. Responses to September 30, 2020 Revised ISR meeting comments.

Comment No.	Agency	Comment	Response
1	FERC	In Section 5.1 of the Revised ISR report it was stated that "Due to overriding safety concerns, Boott limited operation of the turbine units within the downtown canal system during the study period." Can Boott provide better definition of the referenced safety concerns? Is the operation of gates to provide flows through the downtown canal system a normal occurrence when units are offline?	Boott decided to cease operation of the downtown units due electrical hazard concerns for all of the units, in combination with mechanical and other issues with several of the units. The cost to return the units to safe, reliable service was deemed to be economically infeasible relative to the limited amount of generation historically gained from these units. When the downtown units are offline, Boott only operates the canal gates to the extent necessary to manage canal water levels.
2	FERC	In Section 5.1 of the Revised ISR report it was stated that "Flows to the downstream canal system represented between 15-20% of the 2,000 cfs capacity during October and between 20-57% of the 2,000 cfs capacity during November." Can Boott add language to the report to summarize historic canal flows?	Historically, the downtown units have only been operated when there is river flow in excess of the hydraulic capacity of the E.L. Field Powerhouse's two units, typically during spring runoff (March - May). Boott has never directly measured canal flows, and can only estimate flows using the generation records for the downtown units, which are metered separately from the E.L. Field units. For example, for the period 1998 – 2007, estimated average monthly canal flows used for generation were approximately 575 cfs, 800 cfs and 550 cfs for March, April and May respectively. Maximum generation flows for these months were

			approximately 1,500 to 1,600 cfs. Average and maximum generation flows during the eel outmigration period were approximately 90 cfs and 1,200 cfs respectively during October, and 115 and 900 cfs respectively during November.
3	FERC	Can Boott provide a Microsoft Excel file of station operations for the study period to allow for calculation of flow proportions by passage route?	Hourly operations records have been provided in Appendix G and include values for headpond elevation, forebay elevation, tailrace elevation, inflow, Unit 1 discharge, Unit 2 discharge, downstream bypass discharge, upstream fishway flow, downtown canal flow, and spill flow. The reported station operations at the time of downstream passage for each radio-tagged fish were identified. Section 5.7 of the final report has been modified to include a summary of the proportional volume of discharge through the selected passage route relative to non-selected routes (e.g., if a fish passed downstream via the turbines values reported for that individual would include the volume of water passing through the turbines vs. the volume of water passing downstream via alternative routes (i.e., downstream bypass or spill).
4	FERC	Can you provide a summary of the number of events defined for eels in the proportional hazards analysis?	Section 5.10 provides the requested number of events. A total of 144 Pawtucket Gatehouse and 61 E.L. Field Powerhouse forebay events were defined based on recorded detections of adult American eels during the 2019 study to evaluate the impact of operational parameters on passage success.

5	USFWS	In Section 5.1 of the Revised ISR report it was stated that "The downstream bypass was operated throughout the study period, passing approximately 130 cfs." Can you confirm the discharge through that facility when operated in the full open position?	The downstream bypass facility at E.L. Field was designed to pass up to 2% of the E.L. Field nameplate capacity of 6,600 cfs, or 132 cfs. That value has been corrected where referenced in the final report.
6	USFWS	Were approach velocities at the intake racks calculated for this evaluation?	Approach velocities were not calculated specific to observed passage conditions for radio-tagged silver eels. Discussion of the approach velocities expected at the E.L. Field Powerhouse is provided in the *Fish Passage Survival Study.*
7	NMFS	Is it possible to incorporate light incidence into the hourly passage plots (Revised ISR report Figure 5-10)?	Figure 5-10 of the final report has been updated to reflect diurnal, nocturnal or crepuscular passage events.
8	NMFS	Table 5-1 in Section 5-1 summarizes the percentage of inflow records from the 2019 study period categorized by volume as well as the percentage of time that each volume category is historically exceeded for the months of October and November. Is it possible to consider the study months of October and November as a whole to classify the full study period by flow condition?	Section 5-1 has been updated to include an examination of Merrimack River conditions during the full October 9 – November 30, 2019 study period relative to flow exceedance probabilities.
9	MDFW and NMFS	In their Revised ISR comment letters both MDFW and NMFS commented: *The goal of the juvenile alosine and American eel downstream passage assessments was to determine the Lowell Project's impact on the outmigration of juvenile alosine and adult American eel. The specific objectives included*	As stated in the DLA, Boott has elected to decommission the downtown canal units, and to remove the units and associated canal infrastructure from the new license.

		assessing rates and delay to migration for alosine and evaluation of route specific mortality for American eel. Operation of turbine units in the downtown canal system did not occur during the study for safety reasons. This lack of operation significantly affects the study results and our ability to assess project related impacts. However, it is our understanding that the canal units will be decommissioned, as stated by CRP during a conference call with us and the US Fish and Wildlife Service on November 16, 2020. Decommissioning of the canal units should be confirmed in the Draft License Application. If confirmed, then additional evaluation of project impacts related to the canals are not necessary. However, is there is a change in this decision and the downtown canal units are part of the proposed action within the Draft License Application, then the agencies intend to request a second year of study once the canal units are fully operational to determine post-spawned adult alosine and American eel downstream migration route selection, passage efficiency, and residence duration associated with the power canal under various operational conditions, including a range of spill conditions.	

Appendix F. Project inflow and discharge by potential passage route at the time of downstream passage for radio-tagged silver eels at Lowell.

Table of Contents

List of Tables ..... **v**

List of Figures ..... **xi**

1 Introduction **15**

2 Objectives **16**

3 Project Description and Study Area **17**

4 Methods **20**

4.1 Telemetry Equipment **20**

4.2 Monitoring Stations **21**

4.3 Tagging and Release Procedures **27**

4.3.1 Upstream Release Procedures 27

4.3.2 Downstream Release Procedures 27

4.4 Data Collection **28**

4.4.1 Stationary Telemetry Data 28

4.4.2 Manual Telemetry Data 28

4.4.3 Operational and Environmental Data 28

4.4.4 Downstream Drift Assessment 29

4.5 Data Analysis – Upstream Passage **29**

4.5.1 Fish Movement and Project Area Usage 29

4.5.2 Parameter Estimates for Evaluation of Upstream Passage Effectiveness 31

4.5.3 Time to Event Analysis 32

4.6 Data Analysis – Downstream Passage **34**

4.6.1 Parameter Estimates for Evaluation of Downstream Passage 34

4.6.2 Time to Event Analysis – Downstream Passage 36

5 Results **43**

5.1 Merrimack River Conditions and Lowell Project Operations **43**

5.2 Monitoring Station Functionality **47**

5.3 Downstream Drift Assessment **49**

5.4 Upstream Passage Effectiveness – Adult Alewives **51**

5.4.1 Post-Release Movements 51

5.4.2 Approach Duration and Time at Large 51

5.4.3 Foray and Entrance Events 52

5.4.4 PIT-Tagged Individuals 54

5.4.5 Upstream Passage Effectiveness – Lowell Fish Lift 55
5.4.6 Upstream Passage Effectiveness – Lowell Fish Ladder 55
5.5 Upstream Passage Effectiveness – Adult American Shad 75
5.5.1 Post-Release Movements 75
5.5.2 Approach Duration and Time at Large 76
5.5.3 Foray and Entrance Events 76
5.5.4 PIT-Tagged Individuals 77
5.5.5 Upstream Passage Effectiveness – Lowell Fish Lift 78
5.5.6 Upstream Passage Effectiveness – Lowell Fish Ladder 78
5.6 Downstream Passage Effectiveness – Adult Alewives 89
5.6.1 Project Arrival and Upstream Residence Duration 89
5.6.2 Downstream Passage 91
5.6.3 Downstream Transit 92
5.6.4 Passage Survival 92
5.7 Downstream Passage Effectiveness – Adult American Shad 107
5.7.1 Project Arrival and Upstream Residence Duration 107
5.7.2 Downstream Passage 108
5.7.3 Downstream Transit 109
5.7.4 Passage Survival 109
5.8 Time to Event Analysis 121
5.8.1 Adult Alewives – Downstream 121
5.8.2 Adult American Shad – Downstream 124
5.8.3 Adult Alewives – Upstream 126
5.8.4 Adult American Shad – Upstream 128
5.9 Manual Tracking 131
6 Summary 131
6.1 Adult Alewife 131
6.2 Adult American Shad 133
7 Variances from FERC-Approved Study Plan 135
8 References 136
9 Appendices 137
Appendix A. Tagging and release information for adult alosines for the spring 2020 passage assessment at Lowell. 137
Appendix B. Responses to September 30, 2020 Revised ISR meeting comments. 161

Appendix C. Reported hourly operations information for the Lowell Project for the duration of the 2020 spring telemetry study. 162

Appendix D. Project inflow and discharge by potential passage route at the time of downstream passage for radio-tagged adult alosines at Lowell. 163

Appendix E. Listing of manual tracking detections within the Lowell Project area. 170

Appendix F. Tyngsborough adult river herring releases – comparison of individuals originating at Lawrence vs. Amoskeag Dam. 173

List of Tables

Table 5–1. Frequency of occurrence of river inflow at Lowell (to nearest 1,000 cfs) during 2020 adult alosine passage assessment and corresponding percentage of time flows are historically exceeded. 46

Table 5–2. Summary of downtown canal gate settings and estimated discharge values during the spring 2020 adult alosine telemetry study at Lowell. 47

Table 5–3. Summary of tagging and release information for the downstream drift assessment of adult alewives and American shad released in the Lowell tailrace during the downstream passage assessment, May 7 to June 30, 2020. 50

Table 5–4. Summary of tagging and release information for adult alewives released at Lawrence during the Lowell upstream passage assessment, May 7 to June 30, 2020. 56

Table 5–5. Summary of post-release movement for adult alewives tagged and released downstream of Lowell during spring 2020. 57

Table 5–6. Minimum, maximum, and quartile values of approach duration (hours) for dual-tagged adult alewives released downstream of Lowell during the spring 2020 upstream passage assessment. 57

Table 5–7. Minimum, maximum, and quartile values of upstream transit durations (hours) for dual-tagged adult alewives released downstream of Lowell during the spring 2020 upstream passage assessment. 58

Table 5–8. Minimum, maximum, and quartile values of upstream transit rates (mph) for dual-tagged adult alewives released downstream of Lowell during the spring 2020 upstream passage assessment. 59

Table 5–9. Minimum, maximum, and quartile values of time at large (hours) for dual-tagged adult alewives released downstream of Lowell during the spring 2020 upstream passage assessment. 59

Table 5–10. Minimum, maximum, and quartile values of transit durations (hours) for dual-tagged adult alewives during fish lift forays recorded during the spring 2020 upstream passage assessment. 60

Table 5–11. Minimum, maximum, and mean number of fish lift entrance events per upstream foray for dual-tagged adult alewives recorded during the spring 2020 upstream passage assessment. 60

Table 5–12. Minimum, maximum, and quartile values of transit durations (hours) for radio-tagged adult alewives during fish ladder forays recorded during the spring 2020 upstream passage assessment. 60

Table 5–13. Minimum, maximum, and mean number of fish lift entrance events per upstream foray for dual-tagged adult alewives recorded during the spring 2020 upstream passage assessment. 61

Table 5–14. Number of PIT-tagged adult alewives released at Lawrence and recorded at in the exit channel of the E.L. Field Powerhouse fish lift during the spring 2020 upstream passage assessment. 61

Table 5–15. Number of PIT-tagged adult alewives released at Lawrence and recorded at in the entrance, turn pool and exit of the Pawtucket Dam fish ladder during the spring 2020 upstream passage assessment. 61

Table 5–16. Minimum, maximum, and quartile values for PIT-tagged adult alewives moving within the Pawtucket Dam fish ladder during the spring 2020 upstream passage assessment. 62

Table 5–17. CJS model selection criteria for upstream passage effectiveness of the E.L. Field fish lift for adult alewives at Lowell during spring 2020. 62

Table 5–18. Passage success probability estimates (*Phi)*, standard errors, and likelihood 75 and 95% confidence intervals for dual-tagged adult alewives approaching the E.L. Field fish lift during 2020. 62

Table 5–19. Detection efficiency estimates (*p)*, for monitoring stations installed to detect dual-tagged adult alewives approaching the E.L. Field fish lift during 2020. 62

Table 5–20. CJS model selection criteria for upstream passage effectiveness of the Pawtucket Dam fish ladder for adult alewives at Lowell during spring 2020. 63

Table 5–21. Passage success probability estimates (*Phi)*, standard errors, and likelihood 75 and 95% confidence intervals for dual-tagged adult alewives approaching the Pawtucket Dam fish ladder during 2020. 63

Table 5–22. Detection efficiency estimates (*p)*, for monitoring stations installed to detect dual-tagged adult alewives approaching the Pawtucket Dam fish ladder during 2020. 63

Table 5–23. Summary of tagging and release information for adult American shad released at Lawrence during the Lowell upstream passage assessment, May 7 to June 30, 2020. 79

Table 5–24. Summary of post-release movement for adult American shad tagged and released downstream of Lowell during spring 2020. 79

Table 5–25. Minimum, maximum, and quartile values of approach duration (hours) for dual-tagged adult American shad released downstream of Lowell during the spring 2020 upstream passage assessment. 80

Table 5–26. Minimum, maximum, and quartile values of upstream transit durations (hours) for dual-tagged adult American shad released downstream of Lowell during the spring 2020 upstream passage assessment. 80

Table 5–27. Minimum, maximum, and quartile values of upstream transit rates (mph) for dual-tagged adult American shad released downstream of Lowell during the spring 2020 upstream passage assessment. 81

Table 5–28. Minimum, maximum, and quartile values of time at large (hours) for dual-tagged adult American shad released downstream of Lowell during the spring 2020 upstream passage assessment. 81

Table 5–29. Minimum, maximum, and quartile values of transit durations (hours) for dual-tagged adult American shad during fish lift forays recorded during the spring 2020 upstream passage assessment. 82

Table 5–30. Minimum, maximum, and mean number of fish lift entrance events per upstream foray for dual-tagged adult American shad recorded during the spring 2020 upstream passage assessment. 82

Table 5–31. CJS model selection criteria for upstream passage effectiveness of the E.L. Field fish lift for adult American shad at Lowell during spring 2020. 82

Table 5–32. Passage success probability estimates (*Phi)*, standard errors, and likelihood 75 and 95% confidence intervals for dual-tagged adult American shad approaching the E.L. Field fish lift during 2020. 82

Table 5–33. Detection efficiency estimates (*p)*, for monitoring stations installed to detect dual-tagged adult American shad approaching the E.L. Field fish lift during 2020. 83

Table 5–34. Summary of tagging and release information for adult alewives released upstream of Lowell during the spring 2020 downstream passage assessment. 93

Table 5–35. Minimum, maximum, and quartile values of approach duration (hours) for radio-tagged alewives released upstream of Lowell during the spring 2020 adult alosine passage assessment. 94

Table 5–36. Minimum, maximum, and quartile values of upstream residence duration (hours) for radio-tagged alewives released upstream of Lowell during the spring 2020 adult alosine passage assessment. 94

Table 5–37. Minimum, maximum, and quartile values of time to pass the Pawtucket Gatehouse and enter Northern Canal (hours) for radio-tagged alewives released upstream of Lowell during the spring 2020 adult alosine passage assessment. 95

Table 5–38. Minimum, maximum, and quartile values of Northern Canal residence duration (hours) for radio-tagged alewives released upstream of Lowell during the spring 2020 adult alosine passage assessment. 95

Table 5–39. Downstream passage route selection for radio-tagged alewives released upstream of Lowell during the spring 2020 adult alosine passage assessment. 96

Table 5–40. Quartile conditions of project discharge at the time of downstream passage for radio-tagged adult river herring at the known route of passage and the cumulative sum of discharge at non-passage routes. 96

Table 5–41. Minimum, maximum, and quartile values of travel time (hours) through three separate downstream reaches for radio-tagged alewives following downstream passage at Lowell during the spring 2020 adult alosine passage assessment. 97

Table 5–42. Minimum, maximum, and quartile values of rate of travel (mph) through three separate downstream reaches for radio-tagged alewives following downstream passage at Lowell during the spring 2020 adult alosine passage assessment. 98

Table 5–43. Minimum, maximum, and quartile values for downstream travel duration from Lowell to Lawrence (hours) for radio-tagged alewives released upstream of Lowell during the spring 2020 adult alosine passage assessment. 99

Table 5–44. CJS model selection criteria for survival of alewives at Lowell during the spring 2020 adult alosine passage assessment. 100

Table 5–45. Detection efficiency estimates (p) for monitoring locations installed to detect radio-tagged alewives at Lowell during the spring 2020 adult alosine passage assessment. 100

Table 5–46. Reach-specific survival probability estimates (*phi)*, standard errors, and likelihood 75% and 95% confidence intervals for radio-tagged alewives at Lowell during the spring 2020 adult alosine passage assessment. 101

Table 5–47. Summary of tagging and release information for adult American shad released upstream of Lowell during the spring 2020 downstream passage assessment. 111

Table 5–48. Minimum, maximum, and quartile values of approach duration (hours) for radio-tagged American shad released upstream of Lowell during the spring 2020 adult alosine passage assessment. 111

Table 5–49. Minimum, maximum, and quartile values of upstream residence duration (hours) for radio-tagged American shad released upstream of Lowell during the spring 2020 adult alosine passage assessment. 111

Table 5–50. Minimum, maximum, and quartile values of time to pass the Pawtucket Gatehouse and enter Northern Canal (hours) for radio-tagged American shad released upstream of Lowell during the spring 2020 adult alosine passage assessment. 111

Table 5–51. Minimum, maximum, and quartile values of Northern Canal residence duration (hours) for radio-tagged American shad released upstream of Lowell during the spring 2020 adult alosine passage assessment. 112

Table 5–52. Downstream passage route selection for radio-tagged American shad released upstream of Lowell during the spring 2020 adult alosine passage assessment. 112

Table 5–53. Quartile conditions of project discharge at the time of downstream passage for radio-tagged adult American shad at the known route of passage and the cumulative sum of discharge at non-passage routes. 112

Table 5–54. Minimum, maximum, and quartile values of travel time (hours) through three separate downstream reaches for radio-tagged American shad following downstream passage at Lowell during the spring 2020 adult alosine passage assessment. 113

Table 5–55. Minimum, maximum, and quartile values of rate of travel (mph) through three separate downstream reaches for radio-tagged American shad following downstream passage at Lowell during the spring 2020 adult alosine passage assessment. 113

1 Introduction

A radio-telemetry assessment of the upstream and downstream passage success for adult alewife (*Alosa pseudoharengus*) and American shad (*Alosa sapidissima*) was conducted in support of the relicensing for the Lowell Hydroelectric Project (Lowell or Project), Federal Energy Regulatory Commission (FERC) No. 2790, as identified in the Revised Study Plan (RSP) submitted by Boott Hydropower, LLC (Boott) on January 28, 2019. The approach and methodology described in the RSP for the adult alosine telemetry study was approved with modifications by the FERC in its Study Plan Determination (SPD) letter dated March 13, 2019. In their SPD, FERC staff commented on several points related to the original resource agency study requests and the adult alosine passage study proposed by Boott as part of the PSP.

- Resource agency request for a HI-Z balloon tag turbine survival assessment.
    - FERC recommended no HI-Z balloon tag assessment be conducted during 2019. Information from the radio-telemetry and desktop analyses should provide adequate estimates of project survival. In the event these findings are inconclusive FERC would consider additional study requests.
- Resource agency request to increase the number of dual-tagged (i.e., PIT and radio transmitters) from 150 alewives to 200 alewives and from 180 American shad to 200 American shad.
    - FERC indicated there was no evidence that the originally proposed sample sizes of 150 dual-tagged alewives and 180 dual tagged American shad would be insufficient to meet the goals of the study.
- Resource agency request to release tagged alewives and American shad intended to evaluate upstream passage at Lowell at the Lawrence Project rather than transport by truck to a point further upstream.
    - FERC recommended fish be released at a point further upstream to reduce the potential for fallback downstream of Lawrence immediately following tagging and release.
- Resource agency request for one group of herring to be released after May 20 due to likelihood of blueback herring present at that point in the season.
    - FERC recommended at least one release event occur after May 20.
- Resource agency request to add additional monitoring stations into the bypassed reach to help assess passage effectiveness through the existing concrete weirs.

  - FERC recommended that the spatial layout of the monitoring stations as described in the RSP should provide sufficient information to assess passage through that reach.

- Resource agency request to add an additional stationary receiver along the eastern wall of the E.L. Field tailrace to provide data redundancy.
  - FERC recommended placement of an additional stationary receiver along the eastern wall of the E.L. Field tailrace.

- Resource agency requested that Boott either (1) adjust the detection zone of RSP Station M7 further downstream or (2) add an additional station to ensure detection of fish as they approach the confluence of the bypassed reach and tailrace.
  - FERC recommended that the proposed location for Station M7 described in the RSP be installed in a manner which adequately covered the bypassed reach and tailrace confluence area.

On June 12, 2020 FERC issued a Revised Process Plan and Schedule and Determination on Requests for Study Modifications for the Lowell Hydroelectric Project (Revised PPS). In accordance with the Revised PPS, Boott filed their Revised ISR with FERC on September 30, 2020, which contained a mostly completed report for the Upstream and Downstream Adult Alosine Passage Assessment. Boott held a revised ISR meeting on October 15, 2020 and representatives from FERC, U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), Massachusetts Division of Fisheries and Wildlife (MADFW), Massachusetts Division of Marine Fisheries (MDMF), and the New Hampshire Fish and Game Department (NHFGD) had the opportunity to provide comments. A summary of comments received during the October 15 Revised ISR meeting and the corresponding responses are provided in Appendix B of this report. In addition, additional information gaps identified in Section 7.0 of the Revised ISR have been completed into this Updated Study Report. This final technical report describes the objectives, methodologies and results of the 2020 radio-telemetry assessment to evaluate the upstream and downstream passage of adult alosines at the Lowell Project.

It is important to note that the timing of this field study (April – June 2020) coincided with the rapid onset of the COVID-19 pandemic throughout the United States and that both the States of New Hampshire and Massachusetts were operating under a “stay-at-home” order during that time. Every effort was made to conduct this evaluation as described in the RSP and as approved by FERC in their SPD while still maintaining the health and safety of all Normandeau project staff and Boott operations staff.

2 Objectives

The goal of this study was to assess the behavior, approach routes, passage success, survival, and residence duration of adult American shad and alewives as they encounter the Lowell Project during their upstream and downstream migrations to determine if Project operations negatively impact their survival and production.

Specific objectives focused on upstream passage included:

- Determining route selection and behavior of upstream migrating shad and alewives at the Project under varied operational conditions, including a range of spill conditions;
- Assessing the nearfield attraction to, and entrance efficiency of, the fish lift with the river-side entrance open;
- Evaluating residence or fallback associated with the Pawtucket Gatehouse at the upstream end of the Northern Canal;
- Assessing the nearfield attraction to, and entrance efficiency of, the Pawtucket Dam ladder;
- Evaluating the internal efficiency of the Pawtucket Dam ladder;
- Collection of ladder and lift efficiency data, to include rates of approach to fishway entrances, entry into fishways, and passage under varied operational conditions, including a range of spill conditions; and
- To assess the effects of Project operations on the timing, orientation, routes and migration rates of shad and alewives.

Specific objectives focused on downstream passage included:

- Determining the proportion of post-spawned adults that select the downtown canal system or E.L. Field power canal as a downstream passage route;
- Determining post-spawned adult downstream migration route selection, passage efficiency, and residence duration associated with the power canal under various operational conditions, including a range of spill conditions;
- Comparing rates and measures of residence duration and movement among Project areas and routes utilized (e.g., spill at dam versus power canal); and
- Evaluating mortality of adult alosines passed via each potential route.

3 Project Description and Study Area

The Lowell Project is located at River Mile (RM) 41 on the Merrimack River in the City of Lowell in Middlesex County, Massachusetts, with an impoundment extending approximately 23 miles upstream into Hillsborough County, New Hampshire. The existing Lowell Project consists of: (1) a 1,093-foot-long, 15-foot-high masonry gravity dam (Pawtucket dam) that includes a 982.5-foot-long spillway with a crest elevation of 87.2 feet National Geodetic Vertical Datum 1929 (NGVD 29) topped by 5-foot-high pneumatically-operated crest gates deployed in five independently-operable zones; (2) a 720-acre impoundment with a normal maximum water

surface elevation of 92.2 feet NGVD 29; (3) a 5.5-mile-long canal system which includes several small dams and gatehouses; (4) a powerhouse (E.L. Field) which uses water from the Northern Canal and contains two turbine-generator units with a total installed capacity of 15.0 megawatts (MW); (5) a 440-foot-long tailrace channel; (6) four powerhouses (Assets, Bridge Street, Hamilton, and John Street) housed in nineteenth century mill buildings along the Northern and Pawtucket Canal System containing 15 turbine-generator units with a total installed capacity of approximately 5.1 MW; (7) a 4.5-mile long, 13.8-kilovolt transmission line connecting the powerhouses to the regional distribution grid; (8) upstream and downstream fish passage facilities including a fish elevator and downstream fish bypass at the E.L. Field powerhouse, and a vertical-slot fish ladder at the Pawtucket dam; and (9) appurtenant facilities. At the normal pond elevation of 92.2 feet NGVD 1929 (crest of the pneumatic flashboards), the surface area of the impoundment encompasses an area of approximately 720 acres. The gross storage capacity between the normal surface elevation of 92.2 feet and the minimum pond level of 87.2 feet is approximately 3,600 acre-feet. The Project operates essentially in a run-of-river (ROR) mode using automatic pond level control, and has no usable storage capacity.

The study area for the upstream and downstream adult alosine passage assessment included the mainstem Merrimack River from the upper extent of the Project's impoundment located approximately 23 river miles upstream from the Pawtucket Dam in Litchfield, New Hampshire, to the Lawrence Hydroelectric Project (FERC No. 2800), located approximately 11 river miles downstream of the Pawtucket Dam (Figure 3-1). The Project's downtown canal system and the Hamilton, Assets, Bridge Street and John Street Power Stations were also considered as part of the study area.

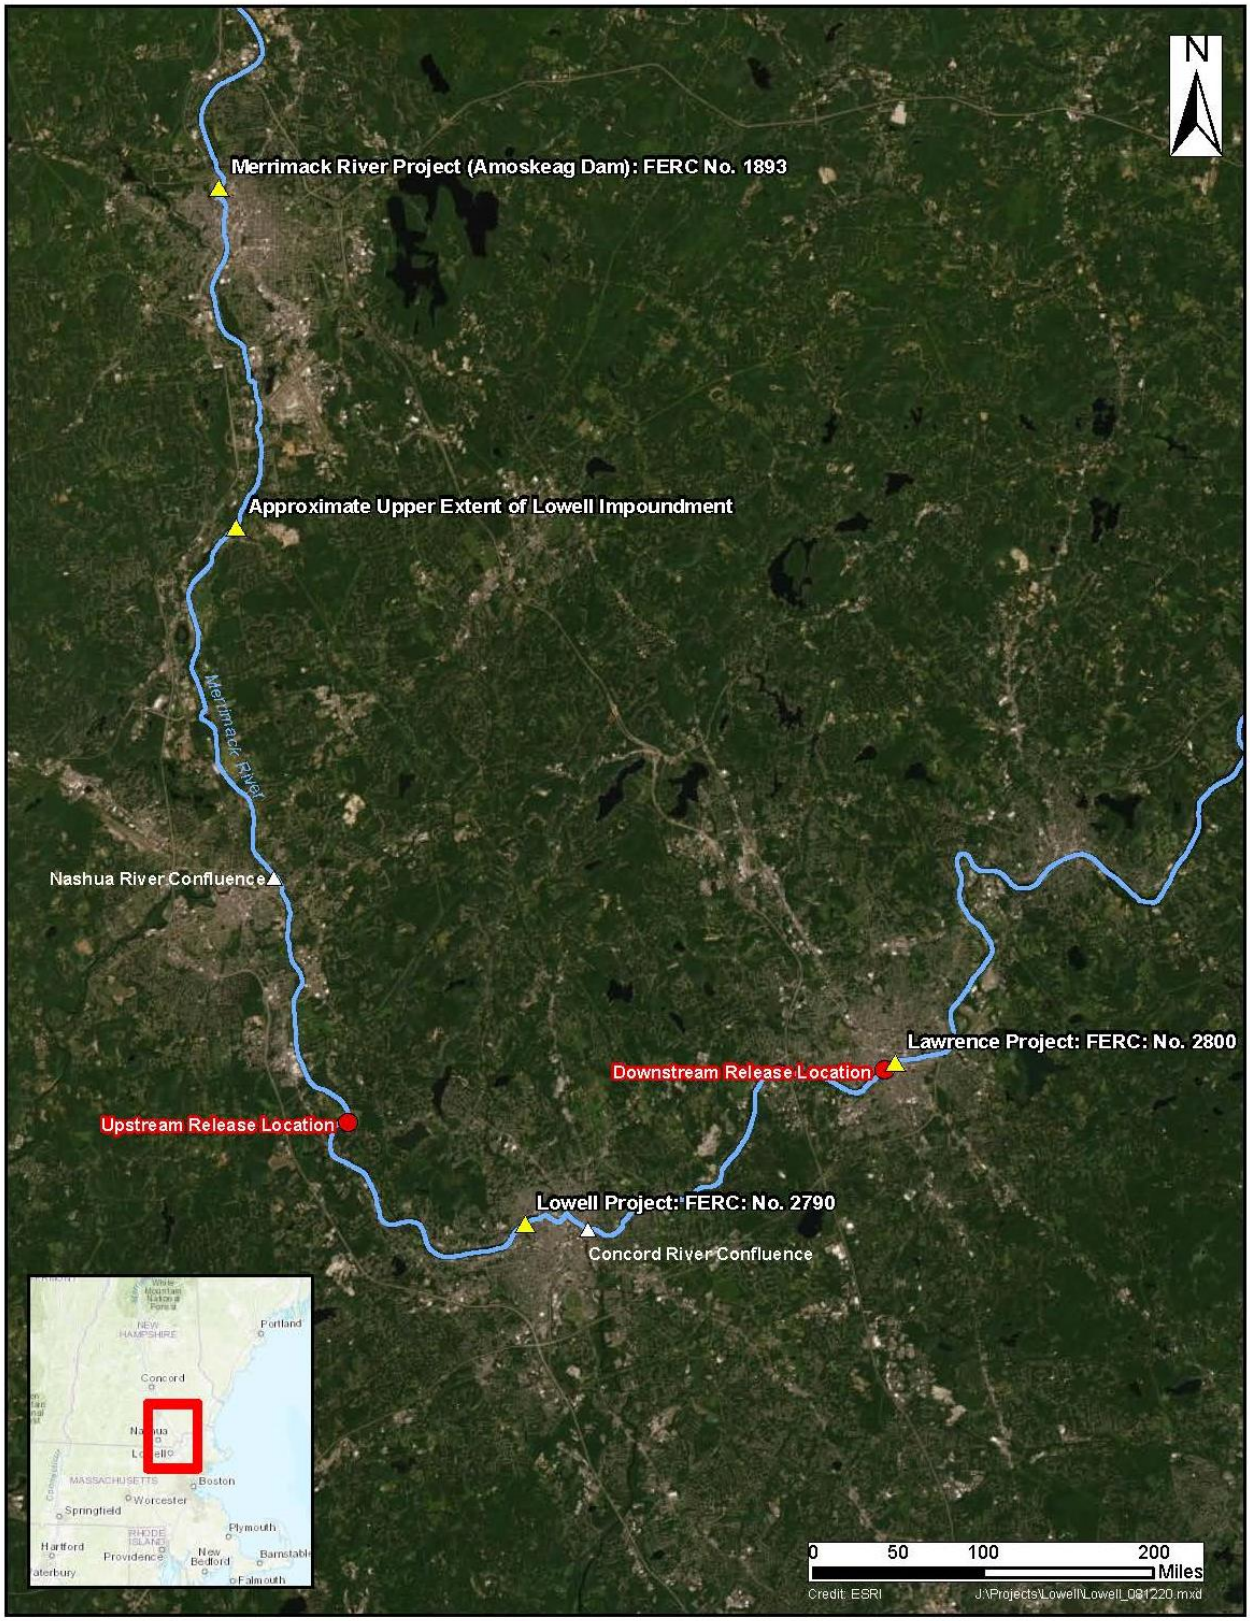

Figure 3–1. Merrimack River study reach considered during the spring 2020 adult alosine upstream and downstream passage assessment.

4 Methods

The upstream and downstream passage of adult alewives and American shad at the Lowell Project was evaluated using radio-telemetry during the spring of 2020. Following the release of radio-tagged individuals into the Merrimack River both upstream and downstream of the Lowell facility, their movements were monitored using a series of stationary radio-telemetry receivers in place at the Project as well as at several additional stationary monitoring receivers installed at bank-side locations upstream and downstream of the Project to inform on general movements, distribution among available passage routes and Project passage success.

4.1 Telemetry Equipment

Movements of radio-tagged individuals during the 2020 study were recorded via a series of stationary PIT[1] and radio-telemetry receivers. Telemetry equipment used during the evaluation of adult alosine passage at Lowell included Orion radio-telemetry receivers, manufactured by Sigma Eight, as well as SRX radio receivers manufactured by Lotek Wireless. Each radio-telemetry receiver was paired with either an aerial or underwater antenna (dropper antenna). Aerial antennas (four or six element Yagi) were utilized to detect radio-tagged individuals within the larger, more open sections of river, such as within the tailrace or at locations downriver of Lowell. Dropper antennas were fixed at downstream passage locations (e.g., downstream bypass). Dropper antennas were custom built by stripping the shielded ends of RG-58 coaxial cables.

Adult American shad and alewives were tagged using transmitters manufactured by Sigma-Eight (model TX-PSC-I-80 or TX-PSC-I-80D) and operating on one of five unique frequencies (149.440, 149.460, 149.480, 149.760, or 149.800 MHz). The TX-PSC-I-80 transmitters measured approximately 10 x 10 x 27 mm, weighed 4.2 g, and had an estimated battery life of 64 days when set at a 2.0 second burst rate. The TX-PSC-I-80D transmitters measured approximately 10 x 10 x 22 mm, weighed 3.3 g and had an estimated battery life of 64 days when set at a 2.0 second burst rate. Each transmitter was coded to emit a unique identifying signal so that individual shad and alewives could be identified by a receiver.

A series of PIT receivers were installed to complement the radio-telemetry array and were placed at locations intended to allow for precise tracking of shad and herring within the Project fishways. The PIT receivers and tags used during 2020 were half-duplex (HDX) and were manufactured by Oregon RFID. Each antenna loop was customized per monitoring site specifics, and equipped with a set of capacitors to properly tune the antenna loop inductance. The HDX PIT tags were encoded by the manufacturer and read only with a 64 bit unique ID. Each cylindrical PIT tag measured 3.65 mm in diameter, 32 mm long, and weighed 0.8g.

[1] Passive Integrated Transponder

4.2 Monitoring Stations

The RSP identified monitoring stations to be set up at Lowell for the spring 2020 adult alosine passage assessment. Each monitoring location identified in the RSP was installed and consisted of a data-logging receiver, antenna, and power source[2]. Receivers were configured to receive transmitter signals from a designated area continuously throughout the study period. During installation of each station, range testing was conducted to configure the antennas and receivers in a manner which maximized detection efficiencies at each location. The operation of receivers was initially established during installation, then confirmed throughout the study period by using beacon tags. A number of beacon tags were stationed at strategic locations within the detection range of either multiple or single antennas, and they emitted signals at programmed time intervals. These signals were detected and logged by the receivers and used to record the functionality of the system throughout the study period.

The locations of monitoring stations installed for the 2020 Lowell adult alosine passage study are outlined here and presented in Figures 4-1 through 4-4.

Monitoring Station 04: Station 04 was installed within the Lowell Project impoundment and was intended to detect radio-tagged adult alosines (1) originally released downstream of Lowell and following successful passage via the fish lift or ladder at the Project, or (2) during their initial movement downstream and away from the upstream release location. Station 04 consisted of a single Lotek SRX radio-receiver and aerial antenna oriented perpendicular to the river channel. It was located approximately 2.1 miles upstream of the Pawtucket Gatehouse and approximately 5.1 miles downstream of the upper release location.

Monitoring Station 05: This station consisted of a single Lotek SRX radio-receiver and an aerial antenna calibrated to provide detection information for radio-tagged alosines (1) originally released downstream of Lowell and following successful passage via the fish lift or ladder at the Project, or (2) originally released upstream as they approached the upstream face of Pawtucket Dam.

Monitoring Station 06: Station 06 consisted of a single Orion radio-receiver and aerial antenna. It was calibrated to provide coverage of the upstream side of the Pawtucket Gatehouse and to inform on (1) radio-tagged alosines originally released downstream of Lowell which had ascended the Project fish lift and successfully exited the Northern Canal via the Pawtucket Gatehouse, or (2) radio-tagged alosines which following a period of residence upstream of the Project had approached the upstream side of the Pawtucket Gatehouse.

Monitoring Station 07: Station 07 consisted of a single Orion radio-receiver and aerial antenna calibrated to provide coverage of the downstream side of the Pawtucket Gatehouse. Station 07 was installed to inform on (1) radio-tagged adult alosines originally released downstream which

[2] Note that three stations identified in the RSP were either modified or eliminated due to logistical issues identified during install, as discussed below. RSP Station M20 was eliminated and replaced with Station M21. RSP Stations C3 and C7 were changed from PIT to radio-telemetry receivers as noted during the ISR meeting in March, 2020.

had ascended the Project fish lift and approached the Pawtucket Gatehouse in an attempt to exit the Northern Canal, or (2) radio-tagged adult alosines which following a period of residence upstream of the Project had successfully passed through the Pawtucket Gatehouse and entered the Northern Canal.

Monitoring Station 08: Station 08 consisted of a single Lotek SRX radio-receiver and aerial antenna installed to provide detection information for radio-tagged adult alosines which were (1) successfully ascended via the fish lift following release downstream, or (2) following a period of residence upstream of the Project had successfully passed through the Pawtucket Gatehouse, entered the Northern Canal and forebay and were in the vicinity of the entrances to the downstream bypass and E.L. Field turbine intake racks.

Monitoring Station 09: Station 09 consisted of a single Orion radio-receiver and underwater drop antenna. It was installed and calibrated to provide detection information for radio-tagged adult alosines which following a period of residence upstream of the Project had successfully passed through the Pawtucket Gatehouse, entered the Northern Canal and forebay, and passed downstream via the downstream bypass.

Monitoring Station 10: This station consisted of a single Lotek SRX radio-receiver and aerial antenna and was installed at a location overlooking the Project tailrace. Detections at this location were used to identify radio-tagged adult alosines which were (1) originally released downstream and subsequently ascended into the Project tailrace and were within the nearfield area of the upstream fish lift, or (2) passed downstream through the turbine units at the E.L. Field Powerhouse following a period of residence upstream of the Pawtucket Dam and within the Northern Canal upstream of the intakes. As stated in the SPD, the installation of an additional stationary receiver along the eastern wall of the E.L. Field tailrace to provide data redundancy was recommended. During the spring installation period, the installation of an additional receiver along the eastern tailrace wall was not conducted due to a lack of safe access during spring flow conditions. Detections from the receiver installed on the backside of the E.L. Field Powerhouse were used for determining presence in the Lowell tailrace.

Monitoring Station 11: Station 11 consisted of a single Lotek SRX radio-receiver and aerial antenna and was installed to scan across the bypassed reach at a point downstream of where the surge gate enters from the power canal and upstream from the downstream bypass. Detections at this location were used to (1) confirm the downstream passage of radio-tagged adult alosines which following a period of residence upstream of the Project passed downstream using the spillway or surge gate, or (2) identify radio-tagged adult alosines released at Lawrence which had initiated an ascent upstream into the bypassed reach. The detection field for Station 11 was centered at a point in the bypassed reach approximately 15% of the distance upstream from the downstream confluence with the tailrace (when considering the full length of the bypassed reach from the entrance to the Pawtucket Dam fish ladder downstream to the confluence with the tailrace).

Monitoring Station 12: Station 12 consisted of a single Lotek SRX radio-receiver and aerial antenna installed to scan across the bypassed reach at a location near to the midpoint of that section. Detections at this location were used to identify radio-tagged adult alosines which had ascended upstream within the bypassed reach. The detection field for Station 12 was centered at a point in the bypassed reach approximately 53% of the distance upstream from the downstream confluence with the tailrace (when considering the full length of the bypassed reach from the entrance to the Pawtucket Dam fish ladder downstream to the confluence with the tailrace).

Monitoring Station 13: Station 13 consist of a single Lotek SRX radio-receiver and aerial antenna installed to scan the upper section of the bypassed reach in close proximity to the entrance to the upstream fishway. Detections at this location were used to identify radio-tagged adult alosines which have ascended the full length of the bypassed reach, were upstream of the concrete weirs and within the nearfield area of the upstream fishway.

Monitoring Stations 14/15: Stations 14 and 15 each consisted of a single half-duplex PIT reader and antenna installed at the first weir upstream from the entrance to the Project fish ladder. These two readers provided fine scale detection information for PIT-tagged adult alosines which had ascended the Project bypassed reach and entered the upstream fishway. The use of two independent PIT readers at this location permitted the install of a pair of smaller loop antennas to monitor each of the two slot openings rather than a single large antenna to try to monitor the full cross section of the fish ladder.

Monitoring Station 16**:** Station 16 was not described in the RSP but was added as a supplement to Stations 14 and 15 during the installation of stationary receivers prior to the spring 2020 study. Station 16 consisted of a single Orion radio-telemetry receiver coupled to an underwater drop antenna positioned inside of the entrance to the Pawtucket Dam fish ladder. This receiver was intended to provide redundant detection information for dual-tagged adult alosines in fish ladder entrance. The drop antenna was positioned upstream of the entrance weir and immediately downstream of the first concrete weir within the lower leg of the fishway.

Monitoring Stations 17/18: Stations 17 and 18 each consisted of a single half-duplex PIT reader and antenna installed at the first weir upstream from the turn pool within the Project fish ladder. These two readers provided fine scale detection information for PIT-tagged adult alosines which had ascended the lower leg of the fishway and were beginning their ascent through the upper leg. Similar to Stations 14/15, the use of two independent PIT readers at this location permitted the install of a pair of smaller loop antennas to monitor each of the two slot openings rather than a single large antenna to try to monitor the full cross section of the fish ladder.

Monitoring Station 19: Station 19 consisted of a single half-duplex PIT reader and antenna. The antenna was installed at the upstream side of the window crowder just downstream from the exit gate at the top of the Pawtucket Dam fish ladder. Installation of the antenna at this

position allowed for the usage of a smaller loop antenna than would be required to attempt to monitor the full cross section of the fish ladder. Station 19 was intended to provide fine scale detection information for PIT-tagged adult alosines which had ascended the Project bypassed reach, entered and successfully navigated the upstream fishway structure.

Monitoring Station 20: Station 20 consisted of a single half-duplex PIT reader and antenna installed to provide detection information for adult alosines which had entered the Lowell fish lift via the river-side entrance. Site conditions prior to the 2020 lift operational season were characterized by high tailwater elevations which prevented the dewatering of the lower entrance flume. As a result, options for installation of the single antenna in the lift entrance were limited. The antenna frame was sized to slide into an existing slot in the wall of the entrance flume just upstream of the riverside entrance weir and was of a size to span the full cross section of the fish lift entrance flume. The watered conditions in the exit flume eliminated the ability to move the antenna frame back and forth within the entrance flume to position at the "sweet spot" for detection range. Construction of two smaller antennas to cover the entrance was not considered due to concerns with a vertical pipe at the center of the entrance flume water column and the potential impact on upstream migrants.

Monitoring Station 21: Station 21 was not described in the RSP but was added during the installation of stationary receivers prior to the spring 2020 study, as a supplement for Monitoring Station 20. Station 21 consisted of a single Orion radio-telemetry receiver coupled to an underwater drop antenna positioned inside of the entrance to the E.L. Field fish lift. This receiver was intended to provide redundant detection information for dual-tagged adult alosines in the lift entrance. The drop antenna was positioned midway between the entrance weir the fish crowder when in its "fishing" position.

Monitoring Stations 22/23: Stations 22 and 23 each consisted of a single half-duplex PIT reader and antenna installed at the upstream end of E.L. Field fish lift exit flume. These two readers provided detection information for PIT-tagged adult alosines which had ascended upstream via the lift and were exiting into the Northern Canal. A pair of independent PIT readers were installed at this location rather than a single large antenna to monitor the full cross section of exit flume to maximize detection probability. Antennas were positioned side by side in the exit flume. During installation the exit flume was dewatered and project staff were able to move the antennas to multiple locations within the channel to identify the location where background interference was minimal.

Monitoring Station 24: Station 24 was installed at a point just downstream of the convergence of flow from the bypassed reach and E.L. Field powerhouse tailrace channel and consisted of a Lotek SRX receiver and aerial antenna. This station provided detection information for radio-tagged adult alosines (1) released at the Lawrence Project as they approach the Lowell Project, and (2) following downstream passage or a period of residence within the tailrace or bypassed reach at the Lowell Project.

Monitoring Station 25: This station was installed at a point along the mainstem of the Merrimack River downstream of both the E.L. Field Powerhouse tailrace and the confluence with the Concord River. Station 25 consisted of a single Lotek SRX receiver and aerial antenna oriented perpendicular to the river channel. This station provided detection information for radio-tagged adult alosines released (1) at the Lawrence Project as they approach the Lowell Project, and (2) following downstream passage or a period of residence within the tailrace or bypassed reach at the Lowell Project. Station 25 was installed at the Lowell Waste Water Treatment Plant, approximately 2.1 miles downstream of the tailrace.

Monitoring Station 26: Station 26 was installed at a commercial business near the midpoint between the Lowell and Lawrence projects and consisted of a single Lotek SRX receiver and aerial antenna oriented perpendicular to the river channel. This station provided detection information for radio-tagged adult alosines released (1) at the Lawrence Project as they approach the Lowell Project, and (2) following downstream passage or a period of residence within the tailrace or bypassed reach at the Lowell Project. Station 26 was located approximately 6.0 miles downstream of the tailrace.

Monitoring Station 27: This station consisted of a single Lotek SRX radio-receiver and an aerial antenna and was installed and calibrated in a manner to provide detection information for radio-tagged adult alosines as they approached the upstream face of Essex Dam (approximately 10.75 miles downstream of the Lowell tailrace).

Monitoring Stations 04 through 27 were installed and maintained throughout the duration of the spring 2020 adult alosine study to inform on the upstream and downstream passage of tagged alewives and American shad at Lowell and within the mainstem of the Merrimack River. An additional seven receivers were described in the RSP and were installed at locations within the Pawtucket Canal system (or “downtown canal” system) as part of this study. Outmigrating adult alosines can potentially enter the Pawtucket Canal system, the entrance of which sits at a point upstream of the Pawtucket Dam and the Northern Canal.

Outmigrating adult alosines entering the Pawtucket Canal first encounter the Guard Locks at a point approximately 1,700 ft downstream from the confluence with the mainstem Merrimack River. Following passage by the Guard Locks, radio-tagged adult alosines are free to move downstream through the Pawtucket Canal until flow diverges and continued passage is possible into either the Western, Merrimack, or Hamilton Canals or the individual can continue downstream in the Pawtucket Canal (via the Swamp Locks). The Western and Merrimack Canals are no longer in use and are essentially deadwater areas and the Assets Power Station (located on the Merrimack Canal) is non-functional and is planned to be eliminated from the new project license. Individuals passing into the Hamilton Canal subsequently enter the Lower Pawtucket Canal via the turbine intakes at the Hamilton Power Station or through the Hamilton Wasteway. From the lower Pawtucket Canal individuals enter into the Eastern Canal. From the Eastern Canal fish can pass into the Concord River via the Bridge Street Power Station or into the Merrimack River via the John Street Power Station or Boott Gate. The Lower Locks is rarely used to pass flow from the Eastern Canal other than for lockage. Monitoring Stations installed

and operated within the downtown canal system during the 2020 adult alosine study consisted of:

Monitoring Station 28: Station 28 was installed to detect outmigrating radio-tagged adult alosines which entered the Pawtucket Canal system rather than pass the Lowell Project via one of the mainstem passage routes. The entrance to the Pawtucket Canal sits at a point upstream of the Pawtucket Dam and the Northern Canal. Station 28 was located at the Guard Locks, approximately 1,700 ft downstream from the entrance to the canal. The monitoring zone for Station 28 was focused downstream of the Guard Locks facility to ensure any detections recorded at that location were of fish which had definitively entered the Pawtucket Canal system. Monitoring Station 28 consisted of a single Orion receiver and aerial antenna.

Monitoring Station 29: Station 29 was installed to detect radio-tagged adult alosines which have moved from the Pawtucket Canal to the Hamilton Canal and reached the Hamilton Power Station. It consisted of a single Orion receiver and antenna coverage at the Hamilton Power Station intake area upstream of the intake for Hamilton Unit 1.

Monitoring Station 30: As described in the RSP, Station 30 was to consist of a single half-duplex PIT reader and antenna and installed at the Hamilton Wasteway located at the downstream end of the Hamilton Canal. During the initial site reconnaissance it was determined that the installation of a PIT antenna was not feasible at this site due to the potential flow volume and the size of the opening and as a result coverage of this route was modified to a single Orion receiver and aerial antenna.

Monitoring Station 31: This station was installed to detect radio-tagged adult alosines which had entered the Eastern Canal and reached the Bridge Street Power Station (a.k.a. “Section 8”). It consisted of a single Lotek receiver and antenna coverage of the Bridge Street Power Station discharge area. Adult alosines successfully passing here had the potential to be subsequently detected downstream at Monitoring Stations 25, 26, and 27.

Monitoring Station 32: Station 32 was installed to detect radio-tagged adult alosines which had entered the Eastern Canal and reached the John Street Power Station. It consisted of a single Orion receiver and antenna coverage at the John Street Power Station intake area.

Monitoring Station 33: Station 33 consisted of a single Orion radio receiver and antenna coverage of the John Street Power Station discharge. Adult alosines successfully passing here had the potential to be subsequently detected downstream at Monitoring Stations 25, 26, and 27.

Monitoring Station 34: As described in the RSP, Station 34 was to consist of a single half-duplex PIT reader and antenna installed at the sluice gate located at Boott Dam. During the initial site reconnaissance it was determined that the installation of a PIT antenna was not feasible at this site due to the potential flow volume and the size of the opening and as a result coverage of this route was modified to a single Orion receiver and aerial antenna. This location provided

coverage to detect any fish departing the Eastern Canal for the Merrimack River during periods of gate operation to flush debris from the lower canal system.

4.3 Tagging and Release Procedures

The majority of adult American shad and alewives were collected for tagging at the Essex Dam fish lift at the Lawrence Hydroelectric Project[3]. Following collection methodology from a previous evaluation of shad movement in the lower Merrimack River (Sprankle, 2005), adult alosines were collected from a net pen placed in the exit flume of the lift which received fish directly from the hopper bucket. Following capture in the net pen, fish were dip-netted out and visually assessed to ascertain their suitability for tagging. Any individuals exhibiting excessive scale loss or other signs of significant stress were not considered for tagging and were released directly into the fish lift exit flume. Individuals deemed acceptable for tagging were quickly measured (total length, nearest mm), and gender was determined (when possible) by gently expressing eggs or milt from running-ripe fish. Radio transmitters were inserted gastrically. To facilitate gastric implantation, transmitters were affixed to a flexible tube with their trailing antenna running through the hollow center. The transmitter and leading edge of the flexible tube were pushed through the mouth and down to the stomach. Once in place, the tube was removed leaving the transmitter antenna trailing from the mouth. PIT tags were implanted into the peritoneal cavity through a small incision on the ventral side of the fish. Adult alosines during this study were either tagged with a radio transmitter (i.e., "radio-tagged"), a PIT tag (i.e., "PIT-tagged") or both a radio and PIT tag (i.e., "dual-tagged").

4.3.1 Upstream Release Procedures

Dual and PIT-tagged adult alosines intended to assess upstream passage effectiveness were released over six dates for alewives and five dates for American shad. All dual and PIT-tagged adult alosines were released directly into the exit flume of the upstream fishway at Lawrence following tagging.

4.3.2 Downstream Release Procedures

Radio-tagged adult alosines intended to assess downstream passage effectiveness were released over four dates for alewives and three dates for American shad. All radio-tagged adult alosines were trucked upstream and released into the Merrimack River at the Tyngsboro Riverfront Park, approximately 7.25 miles upstream of the dam. As described in the RSP, a total of 100 adult alewives and 100 adult American shad were to be radio-tagged and released upstream of the Pawtucket Dam for the purposes of evaluating downstream passage. The RSP had described an additional 50 adult alewives and 50 adult American shad which were to be radio-tagged and released directly into the downtown canal system downstream of the Guard Locks to assess passage through those facilities. Due to overriding safety concerns, Boott had ceased operation of the turbine units within the downtown canal system prior to the study

[3] Note that a subset of adult river herring required for the downstream passage evaluation were collected at Amoskeag fishways. Boott consulted with the resource agencies prior to tagging fish from Amoskeag. Additional details are provided in Section 5.6.

period. Following consultation with the resource agencies, Boott elected to reallocate the transmitters originally purchased for the downtown canal assessment to increase the number of individuals evaluated for downstream passage at the Pawtucket Dam and E.L. Field Powerhouse.

Concurrent with the upstream and downstream adult alosine passage assessment at Lowell, Normandeau Associates simultaneously conducted a separate adult alosine effectiveness study at the Mine Falls Project (FERC No. 3442) on the Nashua River, a tributary to the Merrimack River with a confluence 13.5 miles upstream of the Pawtucket Dam and within the Lowell Project impoundment. Mine Falls is the second dam on the Nashua River, sitting at river mile 5.2, approximately 4.0 miles upstream of the Jackson Mills Project. A total of 100 radio-tagged adult river herring were released upstream of Mine Falls (to be referenced as "Pepperell") and 100 radio-tagged adult river herring were released downstream of Mine Falls (to be referenced as "Mine Falls"). The portion of individuals from those two release groups which were determined to have approached the Pawtucket Dam (based on stationary receiver detections) have been included in this report as part of the assessment of downstream passage.

4.4 Data Collection

4.4.1 Stationary Telemetry Data

Receiver downloads occurred three to four times weekly during the period from the initial tag and release event until the end of June, 2020. Backup copies of all telemetry data were made prior to receiver initialization. Field tests at the time of download to ensure data integrity and receiver performance included confirmation of file integrity, confirmation that the last record was consistent with the downloaded data (beacon tags were critical to this step), and lastly, confirmation that the receiver was operational upon restart and actively collecting data post download. Within a data file, transmitter detections were stored as a single event (i.e., single data line). Each event included the date and time of detection, frequency, ID code, and signal strength.

4.4.2 Manual Telemetry Data

To provide supplemental detection information to the stationary receiver data set, manual tracking was conducted on a number of occasions from the time of initial release through the end of June, 2020. Manual effort was exerted in the vicinity of the Lowell Project (i.e., tailrace and headpond immediately upstream of Pawtucket Dam) on most dates when stationary telemetry equipment was checked. In addition, a number of boat or truck-based efforts were conducted to look for radio-tagged alosines within the Lowell impoundment and the reach of the Merrimack downstream to Lawrence.

4.4.3 Operational and Environmental Data

Hourly records for operations data were provided by Boott for the 2020 evaluation period and included:

- Headpond elevation (ft);

- Power canal elevation (ft);
- Headpond-power canal differential (ft);
- Tailrace elevation (ft);
- Head differential for E.L. Field turbines (ft);
- Total inflow (cfs);
- E.L. Field discharge (cfs);
- Downstream bypass facility discharge (cfs);
- Upstream fishway discharge (cfs);
- Downtown canal flow (cfs); and
- Spill flow through the bypassed reach.

4.4.4 Downstream Drift Assessment

Ten freshly dead adult alewives and ten American shad were radio-tagged and released downstream of Lowell during the 2020 study period. Two individuals were released on each date that a group of live test fish was released upstream of the Pawtucket Dam. Dead, radio-tagged adult alosines were released directly into the discharge of an active turbine unit at the E.L. Field powerhouse. The downstream progression of these known mortalities was recorded by the downstream stationary receivers.

4.5 Data Analysis – Upstream Passage

4.5.1 Fish Movement and Project Area Usage

The tagging, telemetry and Project operations data sets collected as part of this effort were examined and used to evaluate a number of metrics related to upstream passage success and movement through the Project area. These metrics included:

Approach Duration: This value was calculated as the duration of time from release into the Merrimack River at the Lawrence fish lift facility until the initial detection at Monitoring Station 24, the convergence area of the Pawtucket Dam bypassed reach and the E.L. Field tailrace discharge. The duration and rates of upstream ascent for tagged adult alosines from the Lawrence fish lift were further broken down to the discrete sections as bounded by Monitoring Stations 27 to 26, 26 to 25, and 25 to 24. This value was calculated for only dual-tagged individuals.

Time at Large: This value was calculated as the duration of time from the initial detection at Monitoring Station 24 until (1) upstream passage at the Project fish lift or fish ladder, or (2) movement downstream and permanently away from the project area. Final departure times were determined by the last detection at the lift or ladder structures for fish passing upstream or the last detection at Monitoring Station 24 for fish failing to pass and departing downstream. This value was calculated for only dual-tagged individuals.

Foray Events: Foray events were defined for dual-tagged individuals which moved from the convergence area (i.e., the detection zone of Station 24) upstream towards the fish lift or fish ladder as evidenced by detections on one or more receivers along those two routes leading

towards possible upstream passage into the headpond above the Pawtucket Dam. Each event was initiated by a detection at either Station 10 (i.e., E.L. Field tailrace and access to the fish lift) or Station 11 (i.e., the Pawtucket Dam bypassed reach and access to the fish ladder). The duration and magnitude (i.e., most upstream station) of each foray was determined. For individuals which initiated a foray in the direction of the fish lift, each unique event could potentially encompass a sequence of detections at:

- Station 10 – E.L. Field tailrace;
- Stations 20/21 – fish lift entrance;
- Stations 22/23 – fish lift exit flume;
- Station 08 – E.L. Field forebay;
- Station 07 – downstream side of the Pawtucket Gatehouse;
- Station 06 – upstream side of the Pawtucket Gatehouse;
- Station 05 – Merrimack River immediately upstream of the Pawtucket Dam; and
- Station 04 – Merrimack River approximately 2.0 miles upstream of the Pawtucket Dam.

For individuals which initiated a foray in the direction of the fish ladder, each unique event could potentially encompass a sequence of detections at:

- Station 11 – lower portion of the Pawtucket Dam bypassed reach;
- Stations 12 – mid-point of the Pawtucket Dam bypassed reach;
- Stations 13 – upstream end of the Pawtucket Dam bypassed reach;
- Station 14/15/16 – fish ladder entrance;
- Station 17/18 – fish ladder turn pool;
- Station 19 – fish ladder exit;
- Station 05 – Merrimack River immediately upstream of the Pawtucket Dam; and
- Station 04 – Merrimack River approximately 2.0 miles upstream of the Pawtucket Dam.

Entrance Events: The total number of unique entrance events within each defined foray event for a dual-tagged adult alosines approaching either the lift or fish ladder was determined. This process relied on the ability to identify the breaks in the detection time series for a particular individual to indicate when that fish was or was not present in the vicinity of an entrance receiver. Initial attempts to determine the appropriate threshold interval for coverage of the two entrances (i.e., lift or ladder), the intervals between all successive detections at those two locations were calculated by individual and foray event. A threshold interval for determining continued presence was identified as the 97th percentile of the observed set of interval durations. However, due to overlap in receiver coverage, tagged individuals had the opportunity to be detected by both the entrance receiver and the adjacent receiver above or below. This resulted in entrance detection intervals that were heavily inflated by rapid, alternating detections between sites skewing the 97th percentile threshold and overestimating the number of entrance events. To remove the impact of double coverage and alternating site detections and more accurately capture unique entrance events, an individual needed to exhibit at least three successive detections at either entrance before moving up or downstream in order to be considered an entry event. It should be noted that the receivers at the lift and

ladder entrances do not provide directional data. As a result, the reported number of "entrance events" calculated for an individual does not necessarily represent the precise number of individual entries at each structure. However, it does provide some insight into how often a tagged fish was in the vicinity of the entrance (either entering or exiting the structure).

4.5.2 Parameter Estimates for Evaluation of Upstream Passage Effectiveness

Upstream passage effectiveness for adult herring and shad at the Project fish lift and fish ladder was estimated using a standard Cormack-Jolly-Seber (CJS) model run for the set of individual encounter histories developed for each dual-tagged individual which was determined to have initiated a foray towards either passage facility. For dual-tagged individuals this approach provided a series of reach-specific "survival" or passage success estimates at the fish lift for:

- Station 10 to Stations 20/21 (tailrace to lift entrance);
- Stations 20/21 to Stations 22/23 (lift entrance to lift exit);
- Stations 22/23 to Station 08 (lift exit to E.L. Field forebay);
- Station 08 to Station 07 (E.L. Field forebay to downstream of Pawtucket Gatehouse); and
- Station 07 to Station 06 (downstream to upstream of Pawtucket Gatehouse).

This approach provided a series of reach-specific "survival" or passage success estimates at the fish ladder for:

- Station 11 to Station 12 (lower to middle of Pawtucket Dam bypassed reach);
- Station 12 to Station 13 (middle to upper Pawtucket Dam bypassed reach);
- Station 13 to Stations 14/15/16 (upper Pawtucket Dam bypassed reach to ladder entrance);
- Stations 14/15/16 to Stations 17/18 (ladder entrance to turn pool); and
- Stations 17/18 to Station 19 (ladder turn pool to exit).

Standard error and confidence bounds for each estimate were generated and those reach-specific estimates or the product of adjacent reach-specific estimates were used to evaluate upstream passage success. At the fish lift, nearfield effectiveness was estimated as the probability of a fish detected at Station 10 (E.L. Field tailrace) to move to Stations 20/21 (fish lift entrance). Internal effectiveness was estimated as the probability of a fish detected at the lift entrance to move to the lift exit (i.e., from Stations 20/21 to Stations 22/23). Total effectiveness for the Lowell fish lift was estimated as the joint probability to move from the E.L. Field tailrace to the lift exit (i.e., (Stn10 to Stn20/21)*(Stn20/21 to Stn22/23)). Additionally, the probability of successful departure from the Northern Canal (i.e., passage upstream and through the Pawtucket Gatehouse) was estimated as the probability to move from Station 07 to Station 06.

At the fish ladder, nearfield effectiveness was estimated as the probability of a fish detected at Station 13 (upper Pawtucket Dam bypassed reach) to move to Stations 14/15/16 (fish ladder entrance). Internal effectiveness was estimated as the joint probability of a fish detected at the ladder entrance to move to the ladder exit (i.e., (Stn14/15/16 to Stn17/18)*(Stn17/18 to Stn19)). Total effectiveness for the Lowell fish ladder was estimated as the joint probability to

move from the upper Pawtucket Dam bypassed reach to the ladder exit (i.e., (Stn13 to Stn14/15/16)*(Stn14/15/16 to Stn17/18)*(Stn17/18 to Stn19)).

To evaluate upstream passage effectiveness using the CJS models, a suite of candidate models were developed in Program MARK (White and Burnham 1999) based on whether survival (i.e., passage success), recapture (i.e., detection), or both vary or are constant among stations. Models developed during this study included:

- Phi(t)p(t): survival and recapture may vary between receiver stations;
- Phi(t)p(.): survival may vary between stations; recapture is constant between stations;
- Phi(.)p(t): survival is constant between stations; recapture may vary between stations;
- Phi(.)p(.): survival and recapture are constant between stations;

Where;

- Phi = probability of survival
- p = probability of detection
- (t) = parameter varies
- (.) = parameter is constant

To evaluate the fit of the CJS model, goodness of fit testing was conducted for the "starting model" (i.e., the fully parameterized model) using the function RELEASE within Program MARK. Akaike's Information Criterion (AIC) was used to rank the models as to how well they fit the observed mark-recapture data. Lower AIC values denote a more explanatory yet parsimonious fit than higher AIC values. The model with the lowest AIC value was selected for the purposes of generating passage effectiveness estimates.

4.5.3 Time to Event Analysis

4.5.3.1 Cox Proportional Hazard Model

Utilizing available methodology for quantifying fish passage performance (Castro-Santos and Perry 2012), multi-variate Cox proportional hazard models were developed to assess the impact of various operational and environmental variables on the rate of passage success. Operational variables considered as part of this analysis included:

- Bypassed reach spill flow (i.e., the sum of the Pawtucket Dam fish ladder and inflatable section overflow) (cfs);
- Spill flow (cfs);
- Merrimack River inflow (cfs); and
- Release date.

This assessment on the rate of passage success focused on upstream passage events directed towards the (1) E.L. Field fish lift, and (2) Pawtucket Dam fish ladder.

Regression models for the time to event analyses were constructed using the *coxph*() function from the package "*survival*" in R (R Core Team 2020) and were used to evaluate the rate of

passage success and identify operational hazards at sites which contained a physical barrier or a structure through which tagged individuals would have to navigate upstream of the dam through one of the two possible routes.

The Cox proportional hazard regression can be described as a hazard function to evaluate the proportionate risk at time (t) such that

$$h(t) = h_0(t) \times exp(b_1x_1 + b_2x_2 + \ldots + b_ix_i)$$

where $h(t)$ represents that hazard at a given time point which is equal to the initial or baseline hazard at time 0:00 ($h_0(t)$) multiplied by e (the base of the natural logarithm) to the power of the additive relationship between each covariate (x_i) multiplied by its associated coefficient (b_i).

From the above equation, the relative impact of an operational parameter on the rate of passage success is represented by its associated coefficient. The hazard ratio of a given operational parameter is calculated by exponentiating the coefficient of a given parameter, which represents that multiplicative impact of that parameter. It is important to note that exponentiating these coefficients makes the value relative to a value of 1 (e^0), which represents a baseline of no hazard. For example, if the hazard ratio is greater than 1, e.g., 1.5, that will be interpreted as that covariate increasing the risk of passage failure by a factor of 1.5. Alternatively stated, a hazard ratio of 1.5 indicates that the associated covariate increases the risk by 50% as it is 0.5 greater than 1. In contrast, a hazard ratio below 1, e.g., 0.75, indicates that the associated covariate reduces the risk of passage failure by a factor of 0.75, or 25%. In short, a hazard ratio >1 indicates an increase in the risk of passage failure, a hazard ratio of 1 indicates no significant directional effect on passage, and a hazard ratio <1 indicates a reduction in the risk of passage failure.

4.5.3.2 Model Evaluation and Selection

As is the case with any statistical model, the type of model selected makes inherent assumptions about the nature of the data being modelled. The primary assumption of a Cox proportional hazard model is that the hazards are proportional. However, this assumption is not always appropriate for the data. As a result, the *cox.zph()* function was used during this assessment to assess the validity of the proportional hazard assumption. This function assessed scaled Schoenfield residuals to evaluate whether Cox regression residuals of each covariate in addition to the model as a whole are independent of time. In the event that the Schoenfield residuals are not independent of time, it can be said that the assumption of proportional hazards is violated and a Cox proportional hazards model may be misrepresentative of the true relationships between the selected covariates and passage success.

4.5.3.3 Event Definition

The multi-variate Cox proportional hazard models constructed to assess the impact of various operational and environmental variables on the rate of upstream passage success for adult alewives and American shad incorporated the series of upstream foray events defined for each radio-tagged adult alosine using the methodology described above in Section 4.5.1.

4.6 Data Analysis – Downstream Passage

A complete record of all valid stationary receiver detections for each radio-tagged adult alosine was generated. The pattern and timing of detections in these individual records were reviewed, and a route of passage as well as project arrival and passage times were assigned to each radio-tagged individual. In the instance that a downstream route could not be clearly determined from the collected data, the passage event for that particular fish was classified as 'unknown'.

Where data were available, the approach duration and project residence times were calculated. Values for approach duration were calculated as the duration of time from release until detection at Station 05. Upstream project residence time was defined as the duration of time from the initial detection at Station 05 until the determined time of downstream passage. Time spent immediately upstream of the dam was further evaluated using initial detection times for adult alosines at Monitoring Stations 06 and 07 to provide an understanding of passage times associated with moving through the Pawtucket Gatehouse and entering into the Northern Canal approach to the E.L. Field powerhouse.

4.6.1 Parameter Estimates for Evaluation of Downstream Passage

Downstream passage success at the Project was estimated for adult alosines using a standard Cormack-Jolly-Seber (CJS) model run for the set of individual encounter histories (i.e., the series of detection/no detection through the linear sequence of receivers from upstream to downstream). This approach provided a series of reach-specific "survival" or passage success estimates for:

- Monitoring Station 04 to Monitoring Station 05 (i.e., lower impoundment);
- Monitoring Station 05 (i.e., upstream approach) to downstream passage;
- Downstream passage to Monitoring Station 25 (i.e., first downstream receiver);
- Monitoring Station 25 (i.e., first downstream receiver) to Monitoring Station 26 (i.e., second downstream receiver); and
- Station 26 to Lawrence.

Standard error and confidence bounds for each estimate were generated. The joint probability of three reach survival estimates (i.e., (Lowell to Station 25)*(Station 25 to Station 26)*(Station 26 to Lawrence)) was used as the estimate of total passage survival for the Project. This approach resulted in a mortality estimate that included both background mortality (i.e., natural mortality such as predation) and mortality due to Project effects in the reach extending from Lowell downstream to Lawrence. Thus, the results presented in this report reflect a minimum estimate of survival attributable to Project effects for adult alosines.

To evaluate passage success using the CJS models, a suite of candidate models were developed in Program MARK based on whether survival (i.e., passage success), recapture (i.e., detection), or both vary or are constant among stations. Models developed during this study included:

- *Phi(t)p(t)*: survival and recapture may vary between receiver stations;

- *Phi(t)p(.)*: survival may vary between stations; recapture is constant between stations;
- *Phi(.)p(t)*: survival is constant between stations; recapture may vary between stations;
- *Phi(.)p(.)*: survival and recapture are constant between stations;

Where;

- *Phi* = probability of survival
- *p* = probability of detection
- *(t)* = parameter varies
- *(.)* = parameter is constant

To evaluate the fit of the CJS model, goodness of fit testing was conducted for the "starting model" (i.e., the fully parameterized model) using the function RELEASE within Program MARK. Akaike's Information Criterion (AIC) was used to rank the models as to how well they fit the observed mark-recapture data. Lower AIC values denote a more explanatory yet parsimonious fit than higher AIC values. The model with the lowest AIC value was selected for the purposes of generating passage effectiveness estimates.

Models were prepared which evaluated downstream passage success of adult alosines at Lowell as follows:

- All adult alewives– based on detection at Station 37, Station 39 and Lawrence;
- Adult alewives originally released at Tyngsborough – based on detection at Station 25, Station 26 and Station 27 (i.e., Lawrence);
- Adult alewives originally released at Mine Falls or Pepperell – based on detection at Station 25, Station 26 and Station 27 (i.e., Lawrence);
- Route-specific adult alewives (turbine or downstream bypass) – based on detection at Station 25, Station 26 and Station 27 (i.e., Lawrence);
- All adult alewives– adjusted for median "travel time" for freshly dead adult alosines released in Lowell tailrace to reach Lawrence (i.e., test fish with downstream travel times in excess of median drift duration manually adjusted to reflect a mortality at the Project);
- All adult shad – based on detection at Station 25, Station 26 and Station 27 (i.e., Lawrence);
- Route-specific adult shad (turbine, downstream bypass, or spill) – based on detection at Station 25, Station 26 and Station 27 (i.e., Lawrence); and

- All adult shad– adjusted for median "travel time" for freshly dead adult alosines released in Lowell tailrace to reach Lawrence (i.e., test fish with downstream travel times in excess of median drift duration manually adjusted to reflect a mortality at the Project).

4.6.2 Time to Event Analysis – Downstream Passage

4.6.2.1 Cox Proportional Hazard Model

Utilizing available methodology for quantifying fish passage performance (Castro-Santos and Perry 2012), multi-variate Cox proportional hazard models were developed to assess the impact of various operational and environmental variables on the rate of downstream passage success for adult river herring and American shad. Operational variables considered as part of this analysis included:

- Merrimack River inflow (cfs);
- Spill flow (cfs);
- Downstream bypass facility flow (cfs);
- Release location (alewives only); and
- Release date.

This assessment on the rate of passage success focused on approach events at (1) the Pawtucket Gatehouse (i.e., Station 06), and (2) at the E.L. Field Powerhouse (i.e., Station 08).

Regression models for the time to event analyses were constructed using the *coxph*() function from the package "*survival*" in R (R Core Team 2020) and were used to evaluate the rate of passage success and identify operational hazards at sites which contained a physical barrier or a structure through which tagged individuals would have to navigate (i.e., the Pawtucket Gatehouse and E.L. Field Powerhouse).

The Cox proportional hazard regression can be described as a hazard function to evaluate the proportionate risk at time (t) such that

$$h(t) = h_0(t) \times exp(b_1x_1 + b_2x_2 + \ldots + b_ix_i)$$

where $h(t)$ represents that hazard at a given time point which is equal to the initial or baseline hazard at time 0:00 ($h_0(t)$) multiplied by e (the base of the natural logarithm) to the power of the additive relationship between each covariate (x_i) multiplied by its associated coefficient (b_i).

From the above equation, the relative impact of an operational parameter on the rate of passage success is represented by its associated coefficient. The hazard ratio of a given operational parameter is calculated by exponentiating the coefficient of a given parameter, which represents the multiplicative impact of that parameter. It is important to note that exponentiating these coefficients makes the value relative to a value of 1 (e^0), which represents a baseline of no hazard. For example, if the hazard ratio is greater than 1, e.g., 1.5, that will be interpreted as that covariate increasing the risk of passage failure by a factor of 1.5. Alternatively stated, a hazard ratio of 1.5 indicates that the associated covariate increases the

risk by 50% as it is 0.5 greater than 1. In contrast, a hazard ratio below 1, e.g., 0.75, indicates that the associated covariate reduces the risk of passage failure by a factor of 0.75, or 25%. In short, a hazard ratio >1 indicates an increase in the risk of passage failure, a hazard ratio of 1 indicates no significant directional effect on passage, and a hazard ratio <1 indicates a reduction in the risk of passage failure.

4.6.2.2 Model Evaluation and Selection

As is the case with any statistical model, the type of model selected makes inherent assumptions about the nature of the data being modelled. The primary assumption of a Cox proportional hazard model is that the hazards are proportional. However, this assumption is not always appropriate for the data. As a result, the *cox.zph()* function was used during this assessment to assess the validity of the proportional hazard assumption. This function assessed scaled Schoenfield residuals to evaluate whether Cox regression residuals of each covariate in addition to the model as a whole are independent of time. In the event that the Schoenfield residuals are not independent of time, it can be said that the assumption of proportional hazards is violated and a Cox proportional hazards model may be misrepresentative of the true relationships between the selected covariates and passage success.

4.6.2.3 Event Definition

To evaluate the impact of operational parameters on passage success, instances of passage success and failure required definition and represent the 'events' (or passage attempts) in this analysis. Ostensibly, the transmitters deployed during this study should transmit a signal that when within range of a particular receiver will be detected every 2.0 seconds. However, various sources of outside noise or areas of poor coverage due to structures, etc. introduce variation into the frequency of detection for a unique transmitters signals. Given that different site locations and receiver types are subject to varying degrees of ambient noise, the duration between successive detections was calculated for each tagged individual at each receiver location. A threshold interval for determining continued presence of a transmitter within the detection zone of a specific receiver was identified as the 95th percentile of the observed set of interval durations. This value was calculated at 3.42 minutes for Station 6 and 5.64 minutes for Station 29. These two threshold values were then used to delineate when each event was started and completed for a tagged individual. The departure of a radio-tagged individual from the detection zone of a particular receiver was determined when the time interval between successive detections exceeded the specific threshold interval for that zone. In addition, if an individual was observed having left the field of detection and was subsequently detected at another site before returning, this was considered as an event regardless of whether or not the fish returned to the field of detection within the limits of the 95th percentile threshold.

From this, a passage failure event (assigned a value of 0) was defined as any duration where all detections lay within the 95th percentile of durations for all individuals at that site. Passage failure represents events in which a tagged individual enters the field of detection at a given site without passing to the next site (i.e., moving downstream) in the system. A passage success event (assigned a status of 1) was defined using the final instance of detection for a tagged individual at a singular site where that tagged individual was next detected at a downstream

receiver (i.e., successfully passed). Passage success/failure (1/0) was used as the status coinciding with time in the Cox proportional hazard models. After defining passage events for every individual, the time duration for the regression was defined as the duration from one event to the next.

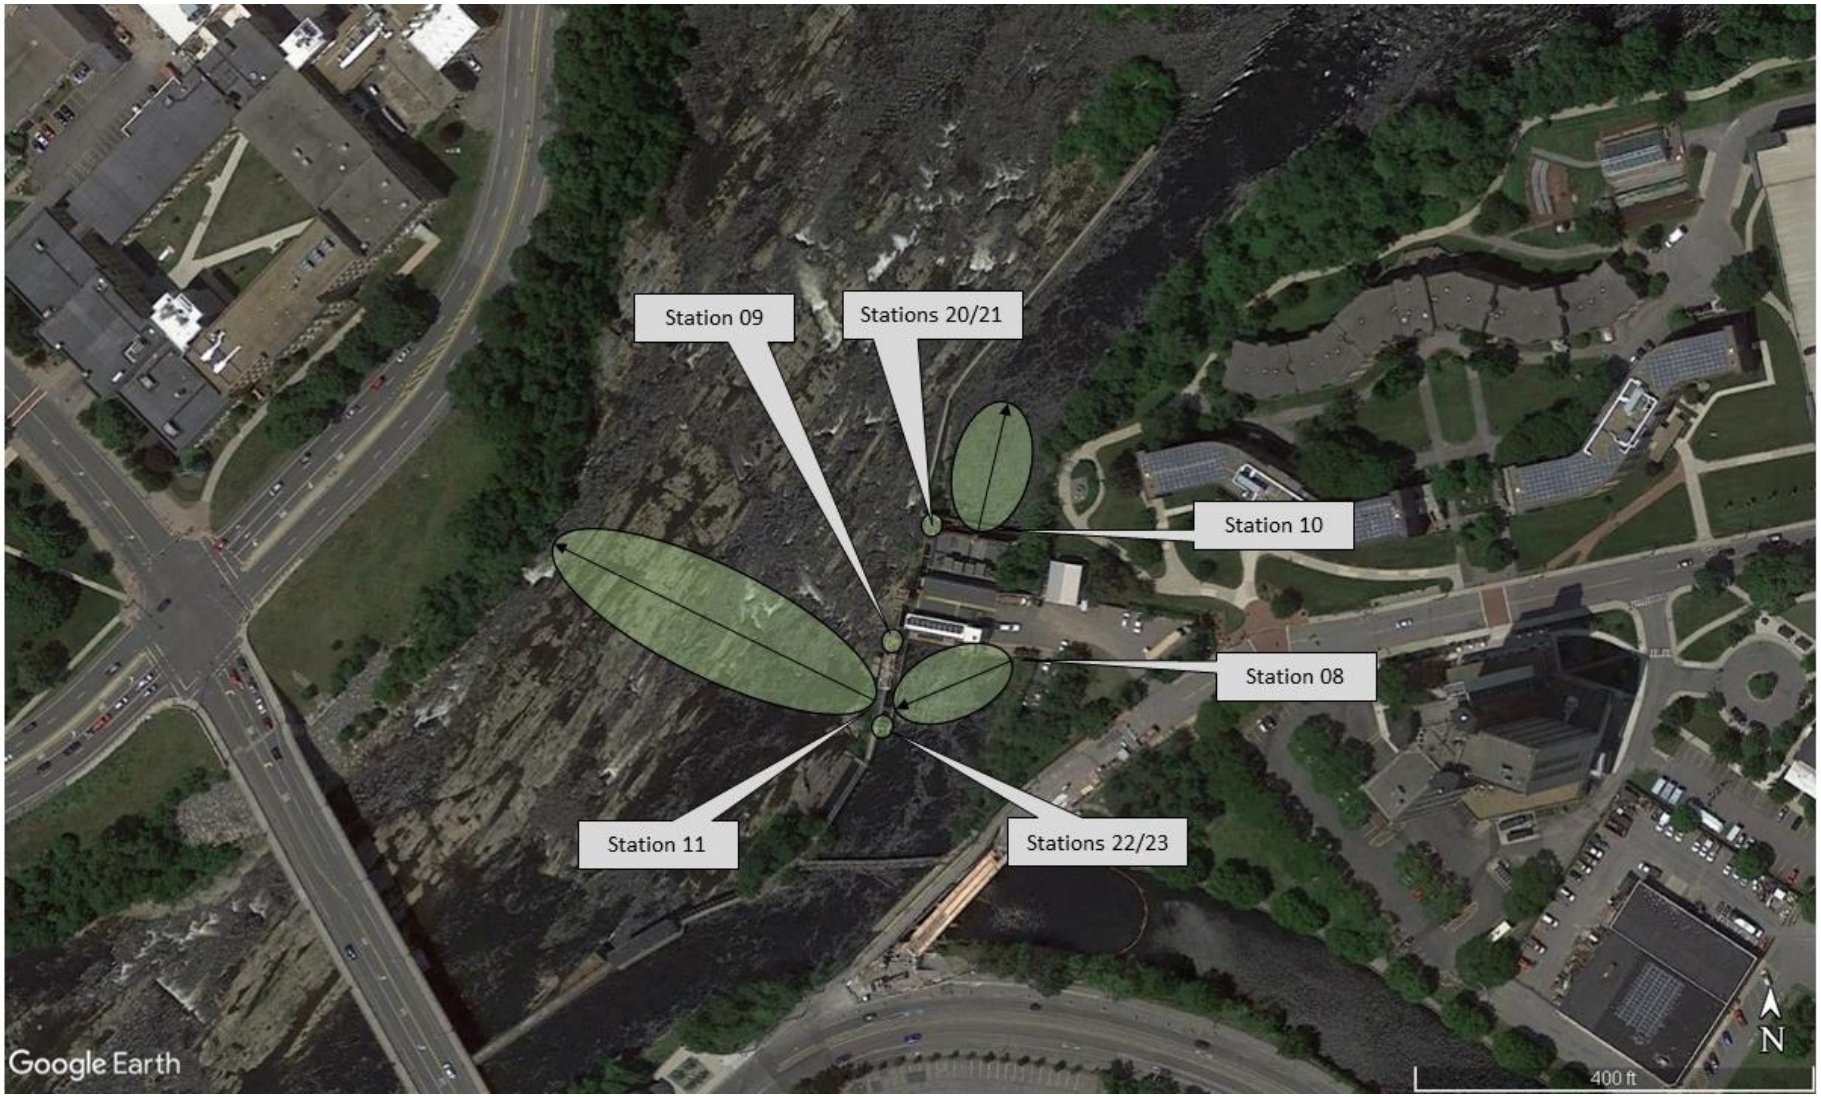

Figure 4–3. Locations and approximate detection areas for stationary radio-telemetry receivers installed in the vicinity of the E.L. Field Powerhouse during the 2020 adult alosine passage assessment at Lowell.

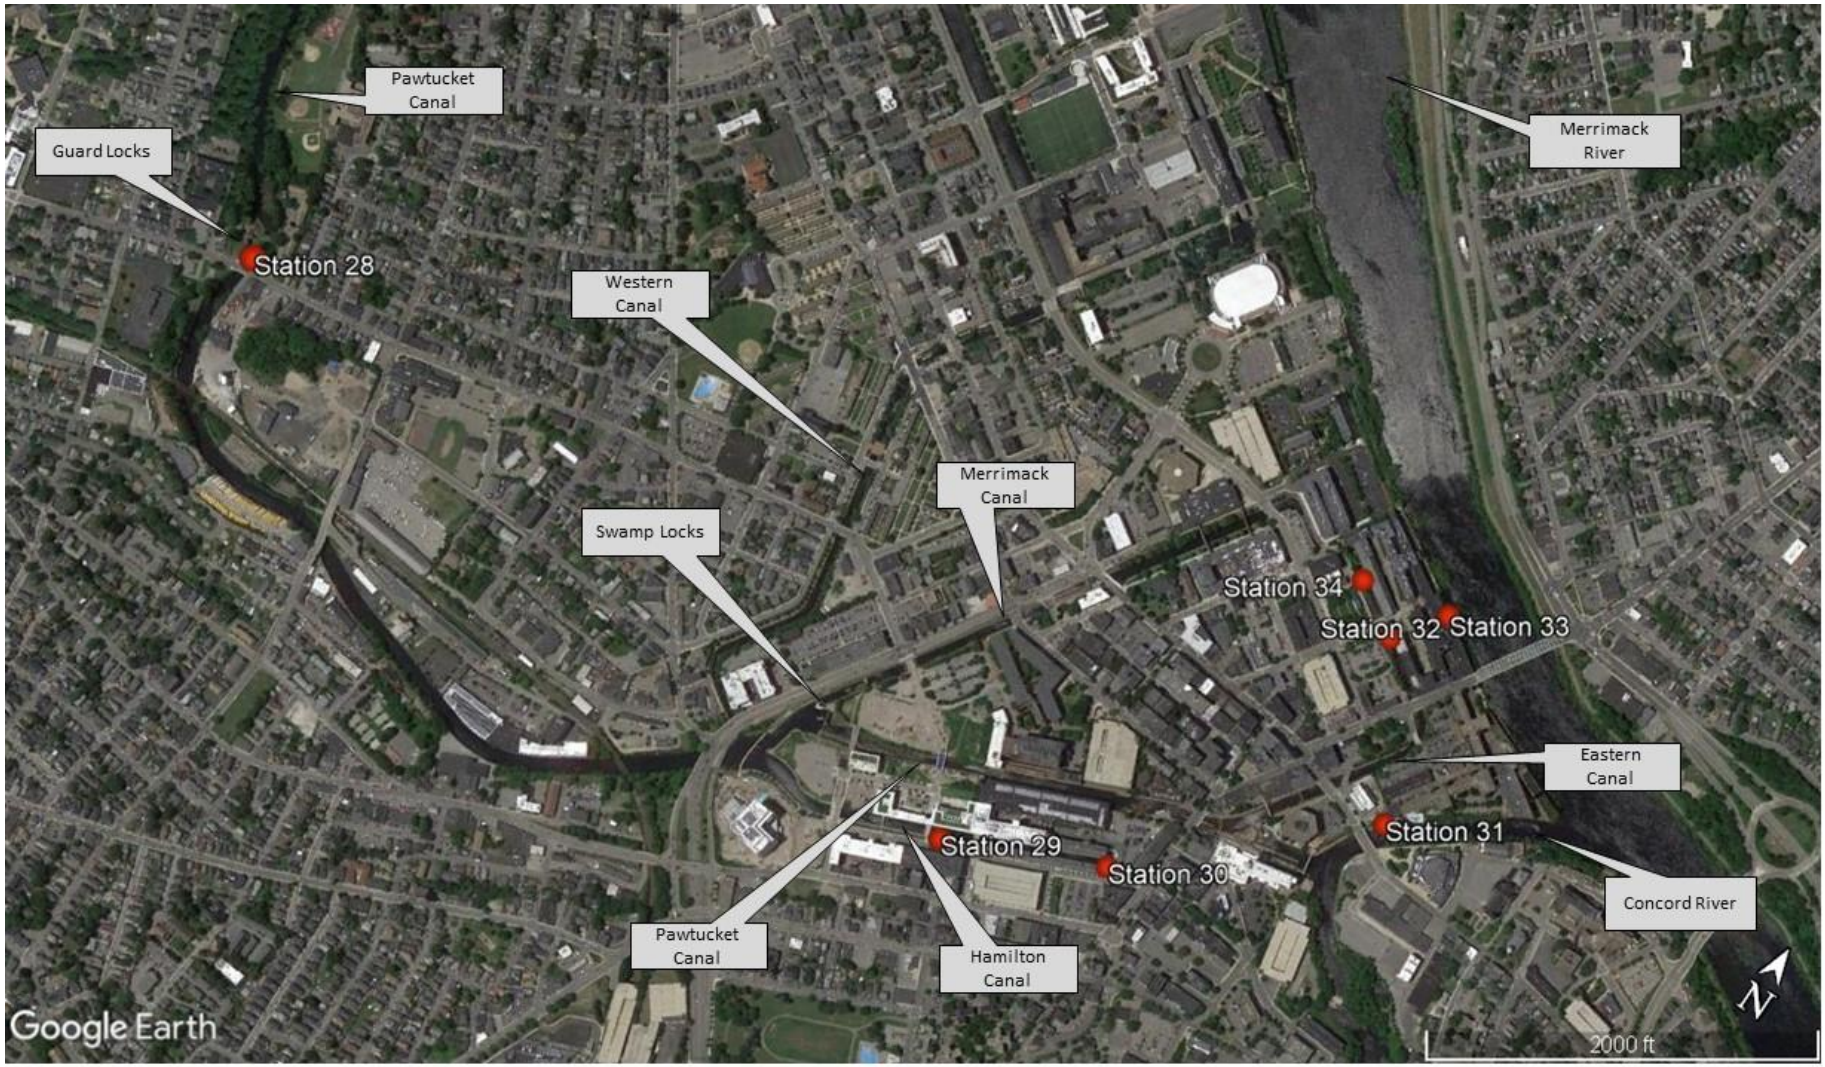

Figure 4–4. Locations and approximate detection areas for stationary radio-telemetry receivers installed within the downtown canal system during the 2020 adult alosine passage assessment at Lowell.

5 Results

5.1 Merrimack River Conditions and Lowell Project Operations

Daily water temperature at Lowell ranged from 8.0-21.1 °C over the course of the monitoring period. Figure 5-1 presents the Merrimack River inflow as recorded at the Lowell Project for the period of time from the first release of tagged adult alosines at Lawrence on May 7 until the end of the monitoring period on June 30, 2020. Merrimack River flow at Lowell ranged between 1,150 and 13,200 cfs during the nearly two month spring study period. Figure 5-2 presents the monthly flow duration curves prepared for the Lowell Project during the development of the Preliminary Application Document. The median flow condition at the Project is approximately 8,900 cfs during May and 4,900 cfs during June. Merrimack River conditions have a ~72% probability during May and a ~35% probability during June to exceed the ~6,600 cfs capacity of the E.L. Field powerhouse.

Table 5-1 summarizes the percentage of inflow records from the 2019 study period categorized by volume (to the nearest 1,000 cfs) as well as the percentage of time that each volume category is historically exceeded[4]. To help characterize the 2020 passage season, monthly exceedance probabilities less than 0.35 were classified as "high" flow conditions, 0.35 to 0.65 were classified as "normal" flow conditions, and greater than 0.65 were classified as "low" flow conditions. Inflows at the Project for the period May 7 through 31 were representative of high flow conditions (i.e., those with a probability of exceedance of less than 0.35) for 6% of the period, normal flow conditions (i.e., those with a probability of exceedance of 0.35-0.65) for 59% of the time and low flow conditions (i.e., those with a probability of exceedance of greater than 0.65) for 35% of the time. For the month of June, inflows were representative of normal flow conditions 7% of the time and low flow conditions 93% of the time.

Flow duration information for the months of May and June (combined) is presented in Figure 5-3. The median flow condition during the two month period is near 6,700 cfs. When characterized using the flow condition criteria above, inflows at the Project for the period May 7 through June 30, 2020 were representative of high flow conditions (i.e., those with a probability of exceedance of less than 0.35) for 7% of the period, normal flow conditions (i.e., those with a probability of exceedance of 0.35-0.65) for 36% of the time and low flow conditions (i.e., those with a probability of exceedance of greater than 0.65) for 57% of the time (Table 5-1).

Figure 5-4 summarizes the allocation of water among the E.L. Field powerhouse, bypassed reach, E.L. Field fish passage facility, Pawtucket Dam fish ladder and the downtown canal system at Lowell. Turbine units were in operation at the E.L. Field powerhouse for the duration of the study period with a brief exception on June 11. The E.L. Field fish passage facilities were

[4] Estimates of monthly exceedance estimated from monthly flow duration curves provided in Appendix H of the PAD.

operated throughout the study period, passing approximately 100 cfs between the hours of approximately 0600 to 1500 and 132 cfs from approximately 1500 to 0600. Two major spill events, associated with increases in river flows, occurred during the early portion of the monitoring period. Peaks for these two high flow events occurred on May 7 and May 18. Outside of those two periods of increased discharge, flows through the bypassed reach during the 2020 monitoring period were comprised of the ~500 cfs of water constituting the attraction and conveyance flow associated with the Pawtucket Dam fish ladder as well as incidental spill flow passing over the spillway. Incidental spill flows in excess of 500 cfs were present until May 21 after which incidental spill was reduced to near zero through the month of June (Figure 5-4).

Flows to the downstream canal system represented between 27-26% of the 2,000 cfs capacity during May and 27% of the 2,000 cfs capacity during June. Due to overriding safety concerns, Boott ceased operation of the turbine units within the downtown canal system prior to the study period. To the extent possible, Boott's operations staff attempted to operate the canal system as if there were canal units available, by opening gates when river flows exceeded the hydraulic capacity of the E.L. Field turbines (6,600 cfs). As a result, flows through the downtown canal system were limited to passage via open gates. Manual gate manipulations during the study period were limited to two dates. A summary of the downtown canal gate operations and discharge is provided in Table 5-2.

Hourly operations records are provided in Appendix C and include values for forebay elevation, tailrace elevation, inflow, E.L. Field turbine discharge, downstream bypass discharge, upstream fishway flow, downtown canal flow, and spill flow.

5.2 Monitoring Station Functionality

Radio-tagged adult alosines were released into the Merrimack River beginning in early May, and the RSP called for continuous monitoring at each stationary receiver location through the end of June, 2020. An overview of system continuity for stationary receivers along the mainstem of the Merrimack and at the E.L. Field Powerhouse is provided in Figure 5-5, for receivers associated with the fish lift and ladder is provided in Figure 5-6, and for receivers positioned at locations in the downtown power canal in Figure 5-7. The majority of the radio-telemetry monitoring stations installed to evaluate passage at Lowell during the spring study operated without issue for the full period.

Interruptions in continuous coverage were observed at two locations among the mainstem and E.L. Field receivers. Station 05 (approach area immediately upstream of Pawtucket Dam) was offline from 1000 on June 4 to 1000 on June 8 due to an internal error in the receiver. To adjust for this outage detection data recorded at Station 06 was reviewed and was used as an approximate for “first detection” of outmigrants approaching the Pawtucket Dam during this period. Station 24 (convergence area of the tailrace and bypassed reach) was offline for three periods during the latter part of May (1500 on May 19 – 1100 on May 20, 1200 on May 20 – 0900 on May 22, and 1300 on May 26 – 1000 on May 27). All components at Station 24 were evaluated after the second interruption (with no obvious cause). The receiver was replaced with a new unit on May 27 and operated without issue for the remainder of the study. To adjust for this outage, detection data from Stations 10 and 11 were used as a surrogate to represent “first detection” downstream of the Project for dual-tagged fish migrating upstream.

Neither outage had an impact on the ability to estimate effectiveness of the upstream fishway facilities or downstream passage survival for adult alosines.

All radio and PIT-readers installed in the E.L. Field fish lift and Pawtucket Dam fish ladder operated without issue for the duration of the study. Over the course of the study there were several minor outages at receiver stations related to the generating units within the downtown canal system. As there was no generation at any of the downtown canal turbine units over the course of the study the overall impact of these short duration outages had no impact on study results.

5.3 Downstream Drift Assessment

Freshly dead, radio-tagged adult alewives (n = 10) and American shad (n =10) were released directly into the discharge of an active turbine unit at the Lowell Project during the 2020 downstream passage assessment. A total of two individuals were released in the tailrace on each date when 20 live radio-tagged adult alewives or American shad were released upstream of the Project. Table 5-3 provides a summary of the body size, tag information, release schedule and flow conditions at the time of release. These individuals were radio-tagged using

a unique frequency (149.360 MHz) and a set of independent receivers were positioned at Monitoring Stations 25, 26, and 27 to scan for the approach and passage of these fish. There were no detections for any of the 20 drift individuals at Stations 25 (2.1 miles), 26 (6.0 miles) or 27 (10.75 miles) downstream of the Lowell tailrace.

Table 5–3. Summary of tagging and release information for the downstream drift assessment of adult alewives and American shad released in the Lowell tailrace during the downstream passage assessment, May 7 to June 30, 2020.

Species	Release Date	River Condition (cfs)		Frequency (ID)	Total Length (mm)
		Inflow	ELF Discharge

				149.360(33)	487
				149.360(34)	506

5.4 Upstream Passage Effectiveness – Adult Alewives

A total of 354 adult alewives were tagged following collection at the Lawrence fish lift during May 2020 and were released for the purposes of evaluating upstream passage at Lowell (Table 5-4). Tagging was conducted over a total of six dates starting on May 7 and ending on May 19. Annual returns for river herring at Lawrence commenced on April 22 and ended on June 15 with significant daily peaks on May 17 and May 28 (Figure 5-8). Looking retrospectively, tagging dates carried out during the 2020 study were conducted during the 5th to 40th percentiles of the annual return. Of the fish tagged, 150 individuals carried both a PIT and radio-transmitter[5] and 204 carried only a PIT tag. Adult alewives tagged for evaluation of upstream passage at Lowell had a sex ratio of nearly 1:1 (51% male, 48% female; 1% undetermined). Total length of individuals tagged ranged from 260-335 mm (mean = 302 mm). A full listing of tagged individuals released at Lawrence during the spring of 2020 is provided in Appendix A.

5.4.1 Post-Release Movements

Adult alewives released downstream of Lowell were free to (1) move upstream and enter into the monitored section of the Merrimack River immediately downstream of the Project, (2) utilize the section of the Merrimack River between Lawrence and Lowell, or (3) fail to move upstream and depart the study reach to downstream of Lawrence. Each dual-tagged individual was classified into a unique post-release movement category based on their pattern of detections among the various monitoring stations. Individuals that were determined to have moved upstream to the project (based on detection at Monitoring Station 24) were classified as "Approached". Individuals that were limited to detections at the monitoring stations downstream of Lowell (i.e., Stations 25 and 26) were classified as "Lower River." Individuals that moved downstream immediately following release (as indicated by a lack of detections at any receivers upstream of Station 27 were classified as "Fallback").

As presented in Table 5-5, the majority of dual-tagged adult alewives were determined to have successfully moved upstream and into the area immediately downstream of the Lowell Project following their release. Of the 150 dual-tagged alewives released, 85% (128 of the 150) were determined to have approached Lowell. A total of 16 dual-tagged adult alewives (11% of all dual-tagged individuals) partially ascended the reach between Lowell and Lawrence but failed to approach the Project. Of those individuals, 50% ascended as far upstream as Station 26 and 50% ascended as far upstream as Station 25. Six dual-tagged individuals were undetected at any of the monitoring stations upstream of Lawrence following their release into the river.

5.4.2 Approach Duration and Time at Large

Adult alewives dual-tagged and released at Lawrence approached Lowell over a range of dates from May 7 (i.e., the first date of downstream releases) until May 23 (Figure 5-9). The median approach duration for dual-tagged adult alewives (i.e., the duration of time from release at Lawrence until initial detection at Station 24) was 19.6 hours (range = 7.7 hours to 11.9 days;

[5] All alewives that were tagged with a radio-tag and a PIT transmitter are referred to as "dual-tagged" in this report.

Table 5-6). When examined by release date, the median approach duration to Lowell was lowest for adult alewives released on May 16 and 17 and highest for those released on May 7 and 8 (Figure 5-10). The minimum, maximum, and quartile transit times through defined sections of the Merrimack River between the release location at Lawrence and the approach receiver (i.e., Station 24) at Lowell are provided in Table 5-7. Transit times calculated using the first detections for each dual-tagged fish at Stations 26, 25, and 24 resulted in median swim times of 5.9 hours from Lawrence to Station 26 (approximately 4.75 miles), 3.5 hours from Station 26 to Station 25 (approximately 3.9 miles) and 2.9 hours from Station 25 to Station 24 (approximately 2.0 miles). Table 5-8 provides the minimum, maximum, and quartile transit times through defined sections of the Merrimack River between the release location at Lawrence and Station 24 as a rate (i.e., miles per hour (mph)).

The duration of time at large following the initial detection at Station 24 for each dual-tagged individual ranged from 1.2 hours to 18.6 days (median = 1.9 days; Table 5-9). For an individual herring, the calculated value for time at large represented time from initial Station 24 detection until either (1) upstream passage out of the study area at the E.L. Field fish lift or the Pawtucket Dam fish ladder, or (2) the final movement downstream and away from the project area. When examined by eventual passage fate (i.e., passed or failed), the median duration of time at large for adult herring successfully passing upstream was less than one half that observed for adult herring which failed to pass upstream (1.7 days vs. 3.9 days, respectively).

5.4.3 Foray and Entrance Events

The full time series of recorded detections for each dual-tagged adult alewife was reviewed and each unique foray upstream towards either the E.L. Field fish lift or Pawtucket Dam fish ladder was identified based on the approach described in Section 4.5. Of the 128 dual-tagged alewives which were determined to have approached Lowell (based on detection at a minimum of Station 24) 95% (121 of the 128) made at least one upstream foray towards either the fish lift or ladder during their time at large in the Project area. Of those dual-tagged alewives, 82 individuals made one or more foray event towards the fish lift and 86 individuals made one or more foray towards the fish ladder. Fifty of the 128 dual-tagged adult alewives were determined to have made at least one foray in the direction of both the fish lift and fish ladder during their time at large in the project area.

5.4.3.1 E.L. Field Fish Lift

The 82 dual-tagged adult alewives determined to have approached the E.L. Field fish lift produced a combined total of 134 unique foray events. When considered on an individual basis, the number of unique lift forays ranged between one and five (mean = 1.6 events). Figure 5-11 summarizes the upstream magnitude for the full set of observed foray events at the fish lift for dual-tagged adult alewives. Approximately 66% of the set of upstream foray events towards the E.L. Field fish lift resulted in detection of the dual-tagged alewife at the lift entrance. Approximately 23% of upstream foray events resulted in dual-tagged adult alewives reaching the downstream side of the Pawtucket Gatehouse. Finally, 17% of the total number of 134 upstream forays in the direction of the E.L. Field fish lift resulting in dual-tagged alewives reached the upstream side of the Pawtucket Gatehouse.

Table 5-10 provides the minimum, maximum and quartile transit times for dual-tagged adult alewives moving upstream during fish lift forays. Upon entering the tailrace detection zone, the median duration of time to locate the fish lift entrance was 0.7 hours (range <0.1 hours to 13.4 hours). The median time to move from the entrance to the exit of the upstream fish lift was 10.4 hours and may be a function of a number of influences including timing of the lift schedule. Upon entering the E.L. Field Power Canal dual-tagged adult alewives proceed quickly upstream to the downstream face of the Pawtucket Gatehouse (median duration = 0.7 hours). The median duration of time for dual-tagged adult alewives to pass the Pawtucket Gatehouse was 25.7 hours (range 0.8 hours to 5.0 days).

Dual-tagged adult alewives were free to be detected at the E.L. Field fish lift entrance multiple times within a single foray event. As noted earlier, approximately 66% of upstream foray events resulted in detection at the fish lift entrance on at least one occasion. The total number of these entrance events were defined for each unique foray event and ranged from one to five (mean = 1.6; Table 5-11). Fish lift entrances were recorded over a range of dates from May 8 through May 30, 2020 (Figure 5-12). The percentage of entrance events peaked during mid-May (approximately May 17 through May 21). The diel distribution of entrance events at the E.L. Field fish lift is presented in Figure 5-13 and indicated dual-tagged alewives initially approached the lift entrance throughout the day with peaks during morning, midday, and late afternoon.

5.4.3.2 Pawtucket Dam Fish Ladder

The 86 dual-tagged adult alewives determined to have approached the Pawtucket Dam fish ladder produced a combined total of 105 unique foray events. When considered on an individual basis, the number of unique fish ladder forays ranged between one and three (mean = 1.2 events). Figure 5-14 summarizes the upstream magnitude for the full set of observed foray events at the fish ladder for dual-tagged adult alewives. The majority of upstream foray events terminated between the lower and upper bypassed reach detection locations (i.e., Stations 11 and 13) with approximately 55% of upstream foray events resulting in detection of the dual-tagged alewife at the upstream end of the bypassed reach. Upon reaching the upstream end of the bypassed reach, the rate of foray failure decreased. Finally, 41% of the total number of 105 upstream forays in the direction of the Pawtucket Dam fish ladder resulted in dual-tagged alewives reaching the ladder exit.

Table 5-12 provides the minimum, maximum and quartile transit times for dual-tagged adult alewives moving upstream during fish ladder forays. Following detection at the lower bypassed reach receiver, the median duration of time to ascend the bypassed reach was 23.6 hours (range = 2.7 hours to 11.7 days). Upon detection at the upper end of the bypassed reach the median duration of time to locate the fish lift entrance was 4.0 hours. Time from initial detection at the fish ladder entrance until exit at the top of the structure ranged from 0.8 hours to 2.0 days (median = 2.9 hours). The median time for dual-tagged adult alewives to transit the lower leg of the fish ladder was 2.1 hours and to transit the upper leg of the fish ladder was 1.1 hours.

Quartile ranges (i.e., P25 to P75) for the mean discharge through the bypass reach during each of the 105 adult alewife foray events were determined using hourly operations data provided by Boott. When examined by upstream magnitude, these ranges overlapped for conditions present for foray events reaching the lower bypassed reach receiver (1,944-3,372 cfs), the middle bypass receiver (954-2,563 cfs), and the upper bypass receiver (2,020-2,176 cfs). The quartile range of mean discharge through the bypass reach for adult herring which successfully passed upstream via the Pawtucket Dam fish ladder was 1,509-3-251 cfs (median = 2,478 cfs).

Dual-tagged adult alewives were free to be detected at the Pawtucket Dam fish ladder entrance multiple times within a single foray event. Approximately 51% of upstream foray events resulted in detection at the fish ladder entrance on at least one occasion. The total number of these entrance events were defined for each unique foray event and ranged from one to three (mean = 1.2; Table 5-13). The average number of entrance detections during a single foray was higher for the earlier release groups of dual-tagged adult alewives. Fish ladder entrances for dual-tagged adult alewives were recorded over a range of dates from May 7 through May 23, 2020 (Figure 5-15). Similar to the fish lift, the percentage of entrance events peaked during mid-May (approximately May 17 through May 21). The diel distribution of entrance events at the Pawtucket Dam fish ladder is presented in Figure 5-16 and indicated dual-tagged alewives initially approached the ladder entrance during the mid-morning, through afternoon hours.

5.4.4 PIT-Tagged Individuals

5.4.4.1 E.L. Field Fish Lift

Limitations detailed for the installation of Monitoring Station 20 in Section 4.2 precluded effective monitoring of PIT-tagged fish at that location. As a result, detection potential for the 204 PIT-tagged adult alewives at the E.L. Field fish lift was limited to the upper exit flume (Stations 22 and 23). PIT-tagged adult alewives were detected at the upper exit flume over a range of dates from May 10 through June 14, 2020 (Figure 5-17). The majority of PIT detections for tagged adult alewives at the lift entrance occurred between 0800 and 1800 with a pronounced peak at 1500 (Figure 5-18). Of the possible 204 PIT-tagged adult alewives, 88 (43%) were determined to have been present in the E.L. Field fish lift exit flume over the course of the study (Table 5-14).

5.4.4.2 Pawtucket Dam Fish Ladder

A total of 204 PIT-tagged adult alewives were released at Lawrence (Table 5-4) and 101 (49.5%) of those individuals were detected at the PIT reader stations installed within the Pawtucket Dam fish ladder (Table 5-15). PIT-tagged adult alewives were detected at the entrance to the Pawtucket Dam fish ladder over a range of dates from May 9 to May 27, 2020 (Figure 5-19). The majority of PIT detections for tagged adult alewives at the fish ladder entrance occurred between 0900 and 1800 (Figure 5-20). Of the 101 PIT-tagged adult alewives detected at the entrance reader, 94% (95 of the 101) were subsequently detected at the turn pool reader and 68% of those (65 of the 95) were subsequently detected at the exit reader. Table 5-16 provides the transit durations for PIT-tagged adult alewives based on initial detections at the entrance, turn pool and exit readers. The median duration to transit the lower leg of the fish ladder was 1.6 hours and to transit the upper leg of the fish ladder was 1.2 hours. The median duration for

a PIT-tagged alewife to move from the Pawtucket Dam fish ladder entrance to the exit was 3.8 hours.

5.4.5 Upstream Passage Effectiveness – Lowell Fish Lift

The CJS model *Phi*(t)*p*(t) provided the best fit for the observed mark-recapture data associated with upstream movements of dual-tagged adult alewives approaching the E.L. Field fish lift (Table 5-17). Specific passage success estimates at Lowell ranged between 0.527- 1.0 among discretely monitored river sections from the tailrace to the point upstream of the Pawtucket Gatehouse (Table 5-18). The detection efficiency for receivers associated with upstream passage of dual-tagged adult alewives at the fish lift ranged from 0.724-1.0 (Table 5-19). The lowest detection value was associated with the two PIT readers positioned in the exit flume of the upstream fishway.

As defined in Section 4.5.2, the specific passage success estimates obtained from the CJS model for dual-tagged adult alewives approaching the E.L. field fish lift were used to estimate (1) near field attraction, (2) fish lift internal efficiency, and (3) overall fish lift effectiveness. As stated earlier the nearfield attraction rate is the probability of an adult herring to move from the nearfield/tailrace region into the downstream entrance of the lift, the internal efficiency is the probability of an adult herring to move from the lift entrance to the lift exit and the overall efficiency is the probability of an adult herring to move from the tailrace/nearfield region to the upstream exit from the fish lift. Upstream passage effectiveness estimates for dual-tagged adult alewives at the Lowell fish lift during 2020 are as follows:

- Nearfield attraction effectiveness:
  - 83.3% (75% CI = 77.4-88.0%)
- Fish lift internal efficiency:
  - 52.7% (75% CI = 45.0-60.3%)
- Overall fish lift effectiveness:
  - 43.9% (75% CI = 39.3-51.4%)

5.4.6 Upstream Passage Effectiveness – Lowell Fish Ladder

The CJS model *Phi*(t)*p*(t) provided the best fit for the observed mark-recapture data associated with upstream movements of dual-tagged adult alewives approaching the Pawtucket Dam fish ladder (Table 5-20). Specific passage success estimates at Lowell ranged between 0.722-0.930 among discretely monitored river sections from Station 11 in the lower bypassed reach to the exit of the fish ladder upstream of the Pawtucket Dam (Table 5-21). The detection efficiency for receivers associated with upstream passage of dual-tagged adult alewives at the fish ladder ranged from 0.905-1.0 (Table 5-22).

As defined in Section 4.5.2, the specific passage success estimates obtained from the CJS model for dual-tagged adult alewives approaching the Pawtucket Dam fish ladder were used to estimate (1) near field attraction, (2) fish ladder internal efficiency, and (3) overall fish ladder effectiveness. As stated earlier the nearfield attraction rate is the probability of an adult herring to move from the nearfield/upper bypass region into the downstream entrance of the ladder,

the internal efficiency is the probability of an adult herring to move from the ladder entrance to the ladder exit and the overall efficiency is the probability of an adult herring to move from the nearfield/upper bypass region to the upstream exit from the fish ladder. Upstream passage effectiveness estimates for dual-tagged adult alewives at the Pawtucket Dam fish ladder during 2020 are as follows:

- Nearfield attraction effectiveness:
  - 93.0% (75% CI = 87.9-96.0%)
- Fish ladder internal efficiency:
  - 81.3% (75% CI = 75.1-87.5%)
- Overall fish ladder effectiveness:
  - 75.6% (75% CI = 69.2-82.2%)

The CJS model prepared for the assessment of upstream passage effectiveness of the Pawtucket Dam fish ladder also generated an effectiveness estimate for passage of adult alewife through the series of concrete weirs installed in the reach between the ladder entrance and the School Street Bridge. That reach was bracketed by Monitoring Stations 12 and 13 and passage effectiveness for adult alewives through that section was estimated at 91.8% (75% CI = 86.8-95.0%) (Table 5-21).

5.5 Upstream Passage Effectiveness – Adult American Shad

A total of 384 adult American shad were tagged following collection at the Lawrence fish lift during May 2020 and were released for the purposes of evaluating upstream passage at Lowell (Table 5-23). Tagging was conducted over a total of five dates starting on May 16 and ending on May 27. Annual returns for American shad at Lawrence commenced on May 5 and ended on June 25 with the peak daily returns occurring during the last week of May (Figure 5-21). Looking retrospectively, tagging dates carried out during the 2020 study were conducted during the 2nd to 32nd percentiles of the annual return. Of the adult shad tagged, 180 individuals carried both a PIT and radio-transmitter and 204 carried only a PIT tag[7]. Adult American shad tagged for evaluation of upstream passage at Lowell were 73% male, 21% female, and 6% undetermined. Total length of individuals tagged ranged from 400-573 mm (mean = 480 mm).

5.5.1 Post-Release Movements

Similar to adult alewives, the American shad tagged and released downstream of Lowell were free to (1) move upstream and enter into the monitored section of the Merrimack River immediately downstream of the Project, (2) utilize the section of the Merrimack River between Lawrence and Lowell, or (3) fail to move upstream and depart the study reach to downstream of Lawrence. Each dual-tagged individual was classified into a unique post-release movement category based on their pattern of detections among the various monitoring stations. Individuals which were determined to have moved upstream to the project (based on detection at Monitoring Station 24) were classified as “Approached”. Individuals which were limited to detections at the monitoring stations downstream of Lowell (i.e., Stations 25 and 26) were classified as “Lower River”. Individuals which moved downstream immediately following release (as indicated by a lack of detections at any receivers upstream of Station 27 were classified as “Fallback”).

As presented in Table 5-24, nearly 40% of dual-tagged adult shad (70 out of 180 individuals) were determined to have successfully moved upstream and into the area immediately downstream of the Lowell Project following their release. The percentage of dual-tagged shad to ascend upstream to the Project was consistent between the sexes (39% of dual-tagged males and 39% of dual-tagged females). The majority of individuals (47% of all dual-tagged individuals) partially ascended the reach between Lowell and Lawrence but failed to approach the Project. Of those individuals, 48% ascended as far upstream as Station 26 (4.75 miles upstream of Lawrence) and 52% ascended as far upstream as Station 25 (8.7 miles upstream of Lawrence). Twenty-five dual-tagged individuals (14% of the total) were undetected at any of the monitoring stations upstream of Lawrence following their release into the river. A portion of a tagged group of adult shad exhibiting fallback behavior immediately following handling and tagging is not unexpected.

[7] All shad that were tagged with a radio-tag and a PIT transmitter are referred to as “dual-tagged” in this report.

5.5.2 Approach Duration and Time at Large

Adult American shad dual-tagged and released at Lawrence approached Lowell over a range of dates from May 17 until June 6 (Figure 5-22). The median approach duration for dual-tagged adult shad (i.e., the duration of time from release at Lawrence until initial detection at Station 24) was 2.7 days (range = 8.4 hours to 29.3 days; Table 5-25). When examined by release date, the median approach duration to Lowell was lowest for adult shad released on May 22 and 26 and highest for those released on May 18 (Figure 5-23). The minimum, maximum, and quartile transit times through defined sections of the Merrimack River between the release location at Lawrence and the approach receiver (i.e., Station 24) at Lowell are provided in Table 5-26. Transit times calculated using the first detections for each dual-tagged fish at Stations 26, 25, and 24 resulted in median swim times of 14.0 hours from Lawrence to Station 26 (approximately 4.75 miles), 23.4 hours from Station 26 to Station 25 (approximately 3.9 miles) and 22.3 hours from Station 25 to Station 24 (approximately 2.0 miles). Table 5-27 provides the minimum, maximum, and quartile transit times through defined sections of the Merrimack River between the release location at Lawrence and Station 24 as a rate (i.e., miles per hour (mph)).

The duration of time at large following the initial detection at Station 24 for each dual-tagged American shad ranged from 0.3 hours to 24.1 days (median = 2.1 days; Table 5-28). For an individual adult shad, the calculated value for time at large represented time from initial Station 24 detection until either (1) upstream passage out of the study area at the E.L. Field fish lift or the Pawtucket Dam fish ladder, or (2) the final movement downstream and away from the project area. When examined by eventual passage fate (i.e., passed or failed), the median duration of time at large for adult American shad successfully passing upstream was nearly equal to that observed for adult shad which failed to pass upstream (2.3 days vs. 1.9 days, respectively).

5.5.3 Foray and Entrance Events

The full time series of recorded detections for each dual-tagged adult American shad was reviewed and each unique foray upstream towards either the E.L. Field fish lift or Pawtucket Dam fish ladder was identified based on the approach described in Section 4.5. Of the 70 dual-tagged shad which were determined to have approached Lowell (based on detection at a minimum of Station 24) 63% (44 of the 70) made at least one upstream foray towards either the fish lift or ladder during their time at large in the Project area. Of those dual-tagged shad, 43 individuals made one or more foray event towards the fish lift and only a single individual made a foray towards the fish ladder.

5.5.3.1 E.L. Field Fish Lift

The 43 dual-tagged adult shad determined to have approached the E.L. Field fish lift produced a combined total of 201 unique foray events. When considered on an individual basis, the number of unique lift forays ranged between one and 20 (mean = 4.7 events). Figure 5-24 summarizes the upstream magnitude for the full set of observed foray events at the fish lift for dual-tagged adult American shad. Approximately 37% of the set of upstream foray events towards the E.L. Field fish lift resulted in detection of the dual-tagged shad at the lift entrance.

Approximately 6% of upstream foray events resulted in dual-tagged adult American shad reaching the downstream side of the Pawtucket Gatehouse. Finally, 3% of the total number of 201 upstream forays in the direction of the E.L. Field fish lift resulted in dual-tagged shad reaching the upstream side of the Pawtucket Gatehouse.

Table 5-29 provides the minimum, maximum and quartile transit times for dual-tagged adult American shad moving upstream during fish lift forays. Upon entering the tailrace detection zone, the median duration of time to locate the fish lift entrance was 1.1 hours (range 0.1 hours to 1.8 days). Upon entering the E.L. Field Power Canal dual-tagged adult shad proceeded quickly upstream to the downstream face of the Pawtucket Gatehouse (median duration = 0.8 hours). The median duration of time for dual-tagged adult shad to pass the Pawtucket Gatehouse was 5.4 days (range 3.3 days to 9.0 days).

Dual-tagged adult shad were free to be detected at the E.L. Field fish lift entrance multiple times within a single foray event. As noted earlier, approximately 37% of upstream foray events resulted in detection at the fish lift entrance on at least one occasion. The total number of these entrance events were defined for each unique foray event and ranged from one to twenty (mean = 4.6; Table 5-30). Fish lift entrances were recorded over a range of dates from May 18 through June 15, 2020 (Figure 5-25). The percentage of entrance events peaked during late-May (approximately May 28 through May 30). The diel distribution of entrance events at the E.L. Field fish lift is presented in Figure 5-26 and indicated dual-tagged shad present at the lift entrance peaked during the mid-morning and early afternoon hours.

5.5.3.2 Pawtucket Dam Fish Ladder

Foray events for dual-tagged adult American shad up the Lowell bypassed reach and towards the Pawtucket Dam fish ladder were limited to a single event. A dual-tagged shad from the May 16 release group was detected at Station 11 in the lower bypassed reach on May 17th. It did not enter the fish ladder.

5.5.4 PIT-Tagged Individuals

5.5.4.1 E.L. Field Fish Lift

Limitations detailed for the installation of Monitoring Station 20 in Section 4.2 precluded effective monitoring of PIT-tagged fish at that location. As a result, detection potential for the 204 PIT-tagged adult American shad at the E.L. Field fish lift was limited to the upper exit flume (Stations 21 and 22). PIT-tagged adult shad were detected at the upper exit flume over a range of dates from May 19 through June 14, 2020 (Figure 5-27). Of the possible 204 PIT-tagged adult shad, 16 (8%) were determined to have been present in the E.L. Field fish lift exit flume over the course of the study.

5.5.4.2 Pawtucket Dam Fish Ladder

Detections at PIT readers within the Pawtucket Dam fish ladder for the 204 PIT-tagged adult shad released at Lawrence were limited to just two individuals. One PIT-tagged adult shad released at Lawrence on May 18 was detected at the fish ladder entrance on May 24 and ascended as far upstream as the turn pool (travel time = 0.8 hours). A second individual

(released at Lawrence on May 26) was detected at the fish ladder entrance reader on June 11 but was not subsequently detected at the turn pool or the ladder exit.

5.5.5 Upstream Passage Effectiveness – Lowell Fish Lift

The CJS model *Phi*(t)*p*(t) provided the best fit for the observed mark-recapture data associated with upstream movements of dual-tagged adult American shad approaching the E.L. Field fish lift (Table 5-31). Specific passage success estimates at Lowell ranged between 0.451- 1.0 among discretely monitored river sections from the tailrace to the point upstream of the Pawtucket Gatehouse (Table 5-32). The detection efficiency for receivers associated with upstream passage of dual-tagged adult American shad at the fish lift ranged from 0.612-1.0 (Table 5-33). Similar to that observed for dual-tagged adult alewives, the lowest detection value was associated with the two PIT readers positioned in the exit flume of the upstream fishway.

As defined in Section 4.5.2, the specific passage success estimates obtained from the CJS model for dual-tagged adult shad approaching the E.L. field fish lift were used to estimate (1) near field attraction, (2) fish lift internal efficiency, and (3) overall fish lift effectiveness. As stated earlier the nearfield attraction rate is the probability of an adult shad to move from the nearfield/tailrace region into the downstream entrance of the lift, the internal efficiency is the probability of an adult shad to move from the lift entrance to the lift exit and the overall efficiency is the probability of an adult shad to move from the tailrace/nearfield region to the upstream exit from the fish lift. Upstream passage effectiveness estimates for dual-tagged adult shad at the Lowell fish lift during 2020 are as follows:

- Nearfield attraction effectiveness:
  - 67.4% (75% CI = 58.8-75.1%)
- Fish lift internal efficiency:
  - 45.1% (75% CI = 34.8-55.8%)
- Overall fish lift effectiveness:
  - 30.4% (75% CI = 22.1-39.5%)

5.5.6 Upstream Passage Effectiveness – Lowell Fish Ladder

Limited number of returns for dual-tagged American shad (see Section 5.5.3.2) prevented the usage of a CJS model to evaluate upstream passage effectiveness of the Pawtucket Dam fish ladder for that species during spring, 2020.

5.6 Downstream Passage Effectiveness – Adult Alewives

A total of 150 adult alewives were radio-tagged and released during late-May and early-June 2020 for the purposes of evaluating downstream passage at Lowell (Table 5-34). Tagging was conducted on a total of four dates starting on May 21 and ending on June 2. Due to observations of reduced daily returns of river herring to the Lawrence Project over the days following the second release group (May 22) adult herring for the last two releases were obtained at the Amoskeag fishway located upstream of the Lowell Project in Manchester, NH[9]. Adult alewives tagged for evaluation of downstream passage at Lowell were comprised of 43% female, 56% male and 1% undetermined. Total length of individuals tagged ranged from 220-330 mm (mean = 294 mm). The mean body length for fish obtained at Lawrence and Amoskeag was similar (295 mm and 292 mm, respectively). A full listing of tagged individuals released upstream of Lowell during the spring of 2020 is provided in Appendix A.

As initially described in Section 4.3.2, a total of 200 radio-tagged adult alewives were released at two locations within the Nashua River, a tributary to the Merrimack River upstream of Lowell. The Pepperell release group consisted of 100 radio-tagged individuals released upstream of Mine Falls and subsequently moved downstream of both Mine Falls and Jackson Mills Dams. The Mine Falls release group consisted of 100 radio-tagged individuals released downstream of Mine Falls and subsequently moved downstream of Jackson Mills (and potentially Mine Falls, dependent on volitional upstream passage there) prior to arrival at Lowell. The subset of radio-tagged adult herring originating in the Nashua River and approaching Lowell (n = 93) has been incorporated into this overall review of downstream passage at the Project.

5.6.1 Project Arrival and Upstream Residence Duration

Releases of radio-tagged adult alewives were initiated upstream of Lowell at the Tyngsborough Riverfront Park on May 21 and concluded on June 2, 2020. Adult herring releases in the Nashua River occurred between the dates of May 17 to 19 for the Mine Falls group and between the dates of May 21 and 28 for the Pepperell release group. Figure 5-28 presents the distribution of arrival dates for those individual radio-tagged herring at the Pawtucket Dam as indicated by detection at Stations 05 and 06. When individuals from all upstream release locations are considered, initial detections for radio-tagged alewives were recorded over a range of dates from May 18 through June 10 with peaks in arrivals on May 30 and June 3, 2020. Radio-tagged individuals released at Mine Falls and Tyngsborough represented the majority of fish arriving through the second half of May and into early June. Later arriving outmigrants recorded approaching Lowell were originally released in the upper Nashua River at Pepperell. The duration of time from release until arrival at Lowell (i.e., the approach duration) ranged from 6.7 hours to 13.4 days (median = 2.4 days) for alewives released at Tyngsborough, from 12.3

[9] See Appendix F for a brief comparison of passage metrics for the adult river herring release groups at Tyngsborough which originated from tagging collections at the Lawrence (n = 80) and Amoskeag Dam (n = 70) fish passage facilities.

hours to 29.3 days (median = 10.3 days) for fish released at Pepperell, and from 3.0 days to 21.4 days (median = 11.4 days) for fish released at Mine Falls (Table 5-35).

The duration of time radio-tagged individuals were present upstream of the Pawtucket Dam was determined for all individuals which approached and eventually passed downstream and was calculated as the duration of time from initial detection immediately upstream of the dam until confirmed downstream passage via one of the available routes. When all individuals are considered, the upstream residence duration prior to downstream passage ranged between 0.4 hours to 8.9 days (Table 5-36; Figure 5-29). The median duration of time spent immediately upstream of the dam structure was 1.8 days and did not appear to differ greatly by release location for radio-tagged adult alewives released at any of the three locations upstream of Lowell (Tyngsborough = 2.0 days; Mine Falls = 1.6 days; and Pepperell = 1.5 days). Of the radio-tagged alewives which approached Pawtucket Dam, 26% passed in less than 24 hours and 78% passed in less than 96 hours after initial detection.

Outmigrating adult alosines encountering the Pawtucket Dam can (1) pass through the Pawtucket Gatehouse and enter the power canal, (2) pass downstream over Pawtucket Dam via spill, or (3) enter the Pawtucket Canal and navigate downstream via the downtown canal system. During the 2020 evaluation only four radio-tagged adult alewives were detected at Monitoring Station 28 indicating those individuals passed downstream through the downtown canal system rather than remaining in the mainstem Merrimack. The majority of radio-tagged alewives were determined to have passed through the Pawtucket Gatehouse and entered the Northern Canal to approach the E.L. Field powerhouse. The duration of time to pass through the Pawtucket Gatehouse was determined based on the initial detection for each individual adult at Stations 06 and 07 which independently monitored the upstream and downstream sides of that structure. The median duration of time for radio-tagged adult alewives to initially encounter and then pass through the Pawtucket Gatehouse was 1.7 hours (range <0.1 hours to 4.1 days; Table 5-37). The quartile ranges (25th to 75th percentiles) did not vary when examined among release groups (0.2-15.3 hours for herring originating at Tyngsborough; 0.1-10.1 hours for fish originating at Mine Falls; and 0.8-13.2 hours for fish originating at Pepperell). The majority (65%) of radio-tagged adult alewives passing through the Pawtucket Gatehouse did so in four hours or less following their initial detection at the structure.

Radio-tagged adult alewives released upstream of Lowell at Tyngsborough and which entered the Northern Canal and passed downstream of E.L. Field powerhouse did so relatively quickly. Of those individuals, 84% were resident in the power canal upstream of E.L. Field for 12 hours or less and the median residence duration in the Northern Canal was 0.5 hours (range = 0.2 hours to 1.8 days; Table 5-38). Adult river herring tagged and released at locations in the Nashua River demonstrated longer residence periods within the Northern Canal prior to downstream passage at Lowell. The quartile ranges (25th to 75th percentiles) for adult herring originally released at Pepperell ranged from 14.5-43.6 hours and for adult herring originally released at Mine Falls ranged from 4.7-69.6 hours (Table 5-38). When all individuals are considered, 20% of adult river herring were present in the Northern Canal for greater than 24 hours prior to downstream passage.

5.6.2 Downstream Passage

A total of 350 radio-tagged adult alewives were released at locations upstream of Lowell during the spring of 2020. Of that total, 124 of the 150 released upstream at Tyngsborough as part of this evaluation were determined to have approached the Pawtucket Dam and were available for the evaluation of downstream passage route (Table 5-39). An additional 93 radio-tagged adult river herring released upstream at Mine Falls (n = 50) and Pepperell (n=43) also approached Lowell and were included in the downstream analysis. The majority of radio-tagged individuals passed through the Pawtucket Gatehouse and approached the E.L. Field powerhouse (92% of approaching fish). Most individuals passed downstream of Lowell via the E.L. Field turbine units (47% of radio-tagged alewives) or utilized the downstream bypass (45% of radio-tagged alewives). Use of the bypassed reach (i.e., spill) was limited to a single individual.

Four radio-tagged adult alewives (2% of all fish approaching Pawtucket Dam) utilized the downtown canal system for downstream passage. The first of two individuals originally released at Tyngsborough and entering the downtown canal system moved through the Pawtucket Canal (i.e., Guard Locks and Swamp Locks) to the Eastern Canal. It was detected at Station 32 in the intake area of the John St. Station prior to passing downstream via the Boott Dam and subsequent detection downstream at Lawrence. Transit time from initial detection at the Guard Locks (Station 28) to passage at Boott Dam was 9.6 hours. The second individual moved through the Pawtucket Canal to Hamilton Canal and passed via the Hamilton Wasteway. It was detected at Station 32 in the intake area of the John St. Station prior to arrival at the receiver monitoring Boott Dam (i.e., Station 34). This individual exited the downtown canal system approximately 16.1 hours following initial detection at the Guard Locks. A single adult river herring originally released at Mine Falls entered the downtown canal system moved through the Pawtucket Canal to Hamilton Canal and passed via the Hamilton Wasteway. It was detected at Station 32 in the intake area of the John St. Station prior to arrival at the receiver monitoring Boott Dam (i.e., Station 34). Transit time from initial detection at the Guard Locks (Station 28) to passage at Boott Dam was 3.1 hours. This individual was subsequently detected downstream at Lawrence (Station 27). The fourth tagged adult river herring documented passing downstream via the downtown canal system was originally released at Pepperell. This individual moved through the Pawtucket Canal (i.e., Guard Locks and Swamp Locks) to the Eastern Canal. It was detected at Station 32 in the intake area of the John St. Station prior to initial detection at the Boott Dam sluice gate 51.9 hours after entering at the Guard Locks. This individual was likely a mortality as it remained stationary in the detection field of Station 34 for over two weeks following initial detection.

The single individual which passed Lowell via spill was initially detected at Station 06 (i.e., immediately upstream of the Pawtucket Gatehouse) but did not pass that structure and enter the Northern Canal.

Radio-tagged adult alewives were observed passing downstream of Lowell between the dates of May 18 through June 19 (Figure 5-30). Downstream passage of radio-tagged adult alosines at Lowell peaked during the early part of June with a peak of downstream passage events

occurring between June 3 and June 6, 2020. Figure 5-31 presents the timing distribution of downstream passage events for radio-tagged adult alewives at Lowell. The majority of individuals passed downstream during the mid-afternoon through early evening hours (i.e., 1400-1900).

For each of the 205 individuals which were confirmed to have passed downstream of Lowell via a known passage route (i.e., turbine, downstream bypass, spill or downtown canal) the hourly record of Project operations (Section 5.1) at the time of passage was reviewed. The discharge at the selected route was identified and contrasted with the cumulative discharge for all non-selected routes at the time of downstream passage (Table 5-40). A total of 47% of radio-tagged adult river herring passing downstream at Lowell did so via the E.L. Field turbine units. The median discharge through the two E.L. Field turbine units at the time of passage for those individuals was 1,853 cfs. When examined by passage route, the median percentage of passage route flow at each known downstream passage route represented 58% of project flow for turbine passed alewives, 4% of project flow for downstream bypass passed alewives, 23% of project flow for spill passed alewives, and 20% of project flow for individuals using the downtown canal system. A listing of route discharge at the time of downstream passage for each adult herring is provided in Appendix D.

5.6.3 Downstream Transit

Three monitoring stations were installed downstream of Lowell for the purpose of detecting radio-tagged adult alosines following passage at the Project during the spring of 2020. Those receivers were located approximately 2.1 (Monitoring Station 25), 6.0 (Monitoring Station 26), and 10.75 (Monitoring Station 27) miles downstream of the project. The minimum, maximum, and quartile transit times through those three reaches are presented in Table 5-41. The median transit time durations for all tagged adult alewives moving downstream of Lowell were 4.7, 2.7, and 17.9 hours for the 2.1 mile, 3.9 mile and 4.75 mile downstream reaches, respectively. When examined by release location the median downstream transit durations were comparable among groups for each reach, ranging from 4.0 to 5.0 hours for adult herring from Lowell to Station 25, 2.6 to 3.3 hours for adult herring from Station 25 to Station 26, and 15.4 to 19.0 hours for adult herring from Station 26 to Essex Dam in Lawrence. Table 5-42 provides the minimum, maximum, and quartile transit times through defined sections of the Merrimack River between Lowell and Lawrence as a rate (i.e., miles per hour (mph)).

Table 5-43 and Figure 5-32 present the minimum, maximum and quartile transit times for radio-tagged adult alewives to cover the full reach from immediately downstream of Lowell to the upstream face of the Essex Dam in Lawrence (i.e., Station 27). The median travel time for those individuals to approach Lawrence following downstream passage at Lowell was 1.1 days (range = 8.0 hours to 7.7 days).

5.6.4 Passage Survival

The CJS model *Phi(t)p(t)* provided the best fit for the observed mark-recapture data associated with downstream movements of all radio-tagged adult alewives approaching and passing at Lowell during 2020 (Table 5-44). The detection efficiency for telemetry receivers recording

passage of adult herring for monitoring stations at Lowell and downstream of Lowell ranged from 1.000 to 0.853 (Table 5-45). The reach-specific survival estimates for the Merrimack River from the Lowell impoundment receiver to detection immediately upstream of Lawrence for (1) all adult alewives, (2) adult alewives released at Tyngsborough, (3) adult alewives released in the Nashua River, (4) turbine-passed adult alewives, and (5) downstream bypass passed adult alewives are presented in Table 5-46. Passage success for downstream passage of adult alewives at Lowell was calculated as the joint probability of the three reach-specific survival estimates which encompasses the full section of the Merrimack River from Lowell downstream to Lawrence (i.e., Lowell to Station 25, Station 25 to Station 26, and Station 26 to Lawrence). This resulted in an estimated downstream passage survival for all adult alewives at Lowell of 80.1% (75% CI = 76.7%-83.6%). No adjustments were made to encounter histories for adult alewives passing Lowell to reflect the duration of time to detection at Lawrence following downstream passage since there were no documented events for radio-tagged "drift" alewives at the downstream receiver stations indicating that the magnitude of downstream travel for that species following dead release into the tailrace was negligible. When examined by release location, downstream passage survival was estimated for adult herring released at Tyngsborough at 76.1% (75% CI = 71.5%-80.5%) and for adult herring released in the Nashua River at 86.2% (75% CI = 81.3%-91.0%).

Radio-tagged adult alewives which approached and passed downstream at Lowell during the 2020 evaluation did so via a variety or passage routes (Table 5-39). Individual CJS models were run for the subset of individuals utilizing the E.L. Field turbine units and downstream bypass facility for downstream passage and produced estimates of 73.9% (75% CI = 68.8%-79.1%) and 87.8% (75% CI = 81.8%-91.5%), respectively. . The single adult alewife passing Lowell via spill and three of the four passing Lowell via the downtown canal system were also subsequently detected at Lawrence.

Table 5–34. Summary of tagging and release information for adult alewives released upstream of Lowell during the spring 2020 downstream passage assessment.

5.7 Downstream Passage Effectiveness – Adult American Shad

A total of 150 adult American shad were radio-tagged and released during early-June 2020 for the purposes of evaluating downstream passage at Lowell (Table 5-47). Tagging was conducted on a total of three dates (June 3, 5, and 8). The New Hampshire Fish and Game Department provided a tank truck to assist with moving radio-tagged shad from the Lawrence lift to the release location upstream of Lowell. Adult shad tagged for evaluation of downstream passage at Lowell were comprised of 37% female, 58% male and 5% undetermined. Total length of individuals tagged ranged from 385-556 mm (mean = 482 mm). A full listing of tagged individuals released upstream of Lowell during the spring of 2020 is provided in Appendix A.

5.7.1 Project Arrival and Upstream Residence Duration

Releases of radio-tagged adult American shad were initiated upstream of Lowell at the Tyngsborough Riverfront Park on June 3, 2020. Figure 5-33 presents the distribution of arrival dates for those individuals at the Pawtucket Dam as indicated by detection at Stations 05 and 06. Initial detections for radio-tagged shad were recorded over a range of dates from June 4 through June 27 with nearly 70% of those fish arriving on or before June 15, 2020. The duration of time from release until arrival at Lowell (i.e., the approach duration) ranged from 13.0 hours to 20.0 days (median = 6.8 days; Table 5-48).

The duration of time radio-tagged individuals were present upstream of the Pawtucket Dam was determined for all individuals which approached and eventually passed downstream and was calculated as the duration of time from their initial detection immediately upstream of the dam until confirmed downstream passage via one of the available routes. When all individuals are considered, the upstream residence duration prior to downstream passage ranged between 0.4 hours to 19.1 days (Table 5-49; Figure 5-34). The median duration of time spent immediately upstream of the dam structure for a radio-tagged adult shad was 3.9 days. Of the radio-tagged adult shad which approached Pawtucket Dam, 30% passed in fewer than 24 hours and 51% passed in fewer than 96 hours after initial detection.

Outmigrating adult alosines encountering the Pawtucket Dam can (1) pass through the Pawtucket Gatehouse and enter the power canal, (2) pass downstream over Pawtucket Dam via spill, or (3) enter the Pawtucket Canal and navigate downstream via the downtown canal system. During the 2020 evaluation there were no radio-tagged adult shad detected at the Guard Locks (Station 28) and determined to have utilized the downtown canal system. The majority of radio-tagged adult shad were determined to have passed through the Pawtucket Gatehouse and entered the Northern Canal to approach the E.L. Field powerhouse. The duration of time to pass through the Pawtucket Gatehouse was determined based on the initial detection for each individual adult at Stations 06 and 07 which independently monitored the upstream and downstream sides of that structure. The median duration of time for radio-tagged adult shad to initially encounter and then pass through the Pawtucket Gatehouse was 2.1 hours (range <0.1 hours to 5.9 days; Table 5-50). The majority (75%) of radio-tagged adult shad passing through the Pawtucket Gatehouse did so in 12 hours or less following their initial detection at the structure.

Radio-tagged adult shad which entered the Northern Canal and passed downstream of E.L. Field powerhouse did so relatively quickly. Of those individuals, 78% were resident in the power canal upstream of E.L. Field for 12 hours or less. The median residence duration in the Northern Canal was 4.4 hours (range = 0.5 hours to 3.0 days; Table 5-51). Five radio-tagged individuals were present in the Northern Canal for greater than 24 hours prior to downstream passage.

5.7.2 Downstream Passage

A total of 150 radio-tagged adult American shad were released upstream of Lowell during the spring of 2020. Of that total, 118 were determined to have approached the Pawtucket Dam and were available for the evaluation of downstream passage route (Table 5-52). Over half of the radio-tagged shad passed through the Pawtucket Gatehouse, approached the E.L. Field powerhouse, and passed downstream via the E.L. Field turbine units (26% of radio-tagged shad) or utilized the downstream bypass (28% of radio-tagged shad). Use of the bypassed reach (i.e., spill or usage of the attraction water gate associated with the upstream fish ladder) was observed for 38% of the radio-tagged adult shad which approached the Project. Of the 45 radio-tagged adult shad which were determined to have passed downstream via the bypassed reach, 89% were initially detected in the area immediately upstream of the Pawtucket Gatehouse prior to downstream passage. Of those same 45 individuals, 9% were determined to have entered and exited the Northern Canal via the Pawtucket Gatehouse prior to their eventual passage downstream via the bypassed reach.

Radio-tagged adult shad were observed passing downstream of Lowell between the dates of June 5 through June 27 (Figure 5-35). Downstream passage of radio-tagged adult shad at Lowell peaked during mid-June with over half of all passage events occurring between June 16 and June 20, 2020. Figure 5-36 presents the timing distribution of downstream passage events for radio-tagged adult shad at Lowell. The majority of individuals passed downstream during the late morning, afternoon and early evening hours (i.e., 1000-2000).

For each of the 109 individuals which were confirmed to have passed downstream of Lowell via a known passage route (i.e., turbine, downstream bypass, or spill) the hourly record of Project operations (Section 5.1) at the time of passage was reviewed. The discharge at the selected route was identified and contrasted with the cumulative discharge for all non-selected routes at the time of downstream passage (Table 5-53). A total of 28% of radio-tagged adult shad passing downstream at Lowell did so via the E.L. Field turbine units. The median discharge through the two E.L. Field turbine units at the time of passage for those individuals was 967 cfs. When examined by passage route, the median percentage of passage route flow at each known downstream passage route represented 46% of project flow for turbine passed shad, 6% of project flow for downstream bypass passed shad, and 33% of project flow for spill passed shad. A listing of route discharge at the time of downstream passage for each adult American shad is provided in Appendix D.

5.7.3 Downstream Transit

Three monitoring stations were installed downstream of Lowell for the purpose of detecting radio-tagged adult alosines following passage at the Project during the spring of 2020. Those receivers were located approximately 2.1 (Monitoring Station 25), 6.0 (Monitoring Station 26), and 10.75 (Monitoring Station 27) miles downstream of the project. The minimum, maximum, and quartile transit times through those three reaches are presented in Table 5-54. The median transit time durations for tagged adult shad moving downstream of Lowell were 6.4, 1.9, and 5.9 hours for the 2.1 mile, 3.9 mile and 4.75 mile downstream reaches, respectively. Table 5-55 provides the minimum, maximum, and quartile transit times through defined sections of the Merrimack River between Lowell and Lawrence as a rate (i.e., miles per hour (mph)).

Table 5-56 and Figure 5-37 present the minimum, maximum and quartile transit times for radio-tagged adult shad to cover the full reach from immediately downstream of Lowell to the upstream face of the Essex Dam in Lawrence (i.e., Station 27). The median travel time for those fish to approach Lawrence following downstream passage at Lowell was 18.5 hours (range = 6.9 hours to 5.6 days).

5.7.4 Passage Survival

The CJS model *Phi(t)p(t)* provided the best fit for the observed mark-recapture data associated with downstream movements of radio-tagged adult American shad approaching and passing at Lowell during 2020 (Table 5-57). The detection efficiency for telemetry receivers recording passage of adult shad for monitoring stations at and downstream of Lowell ranged from 0.987 to 0.859 (Table 5-58). The reach-specific survival estimates for the Merrimack River from the Lowell impoundment receiver to detection immediately upstream of Lawrence are presented in Table 5-59. Passage success for downstream passage of adult shad at Lowell was calculated as the joint probability of the three reach-specific survival estimates which encompasses the full section of the Merrimack River from Lowell downstream to Lawrence (i.e., Lowell to Station 25, Station 25 to Station 26, and Station 26 to Lawrence). This resulted in an estimated downstream passage survival for adult shad at Lowell of 70.0% (75% CI = 64.5%-74.6%). No adjustments were made to encounter histories for shad passing Lowell to reflect the duration of time to detection at Lawrence following downstream passage since there were no documented events for radio-tagged “drift” shad at the downstream receiver stations indicating that the magnitude of downstream travel for that species following dead release into the tailrace was negligible.

Radio-tagged adult shad which approached and passed downstream at Lowell during the 2020 evaluation did so via a variety or passage routes (Table 5-52). Sample sizes for adult shad passing downstream via the turbines, downstream bypass facility or spill through the bypassed reach were sufficient to generate an estimate of downstream passage survival via the CJS model approach. When examined by passage route downstream passage for adult American shad was estimated at:

- E.L. Field Turbines: adult American shad passage success = 35.5% (75% CI = 25.8%-45.2%);

- Downstream bypass facility: adult American shad passage success = 82.6% (75% CI = 75.7%-90.9%); and

- Spill: adult American shad passage success = 89.2% (75% CI = 82.6%-93.8%).

5.8 Time to Event Analysis

5.8.1 Adult Alewives – Downstream

A total of 1,508 Pawtucket Gatehouse and 22,051 E.L. Field Powerhouse forebay events were defined based on recorded detections of radio-tagged adult alewives during the 2020 study to evaluate the impact of operational parameters on passage success. The median event duration recorded for a radio-tagged individual was 3.4 minutes for individuals in the detection field of Station 06 immediately upstream of the Pawtucket Gatehouse and 5.6 minutes for individuals in the detection field of Station 08 covering the area immediately upstream of the E.L. Field intake structure.

5.8.1.1 Pawtucket Gatehouse

Results of the adult alewife Cox proportional hazard model for the Pawtucket Gatehouse were found to be unreliable as all variables failed to obey the assumption that covariates are independent of time and that hazards are proportional (Table 5-60). In an effort to identify any existing correlations between passage success/failure or delay and the operational parameters available, a generalized additive model (GAM) with a Tweedie-distribution and generalized linear model (GLM) with a binomial distribution were built from the package '*mgcv'* in the Program R (R Core Team 2020). These model types permitted flexible parameterization of the error structure and offered an alternative method for exploring the relationships in question under a different suite of model assumptions.

GLMs were constructed as a means of understanding whether event success was correlated with inflow, spill, release location, or release date. The GLM model suggested a statistically significant positive correlation between downstream adult herring passage success and inflow with successful downstream passage events occurring most frequently when inflow is greater than 6000 cfs (Figure 5-38). Additionally, there was a statistically significant negative relationship between release location and downstream adult herring passage success indicating that individuals released in the Nashua River at the Mine Falls release site were less likely to pass downstream of Lowell successfully than either the Tyngsborough or Pepperell release groups (Figure 5-39).

GAMs were built in an attempt to understand which covariates exhibited a significant impact on the duration of each event (i.e. which covariates were responsible for causing delay in successful downstream passage for adult river herring at the Pawtucket Gatehouse). Release date, release location, inflow, bypass flow, and event type (i.e., pass or fail) were included in the GAM as a covariate to assess whether passage success or failure significantly impacted the duration of an event. Although results of this model agreed with that of the GLM, suggesting event duration was positively correlated with inflow and negatively correlated with passage success (i.e. successful passage reduced event duration) these results were considered weak as only 10.7% of the deviance in the data was explained by the model.

Table 5–60. Output of the Schoenfield residual test for time independence of covariates in Cox proportional hazard model for adult river herring Pawtucket Gatehouse downstream passage events.

Variable	Chi-squared	df	P-Value
Release Location	7.00	2	0.03
Release Date	36.32	2	0.07

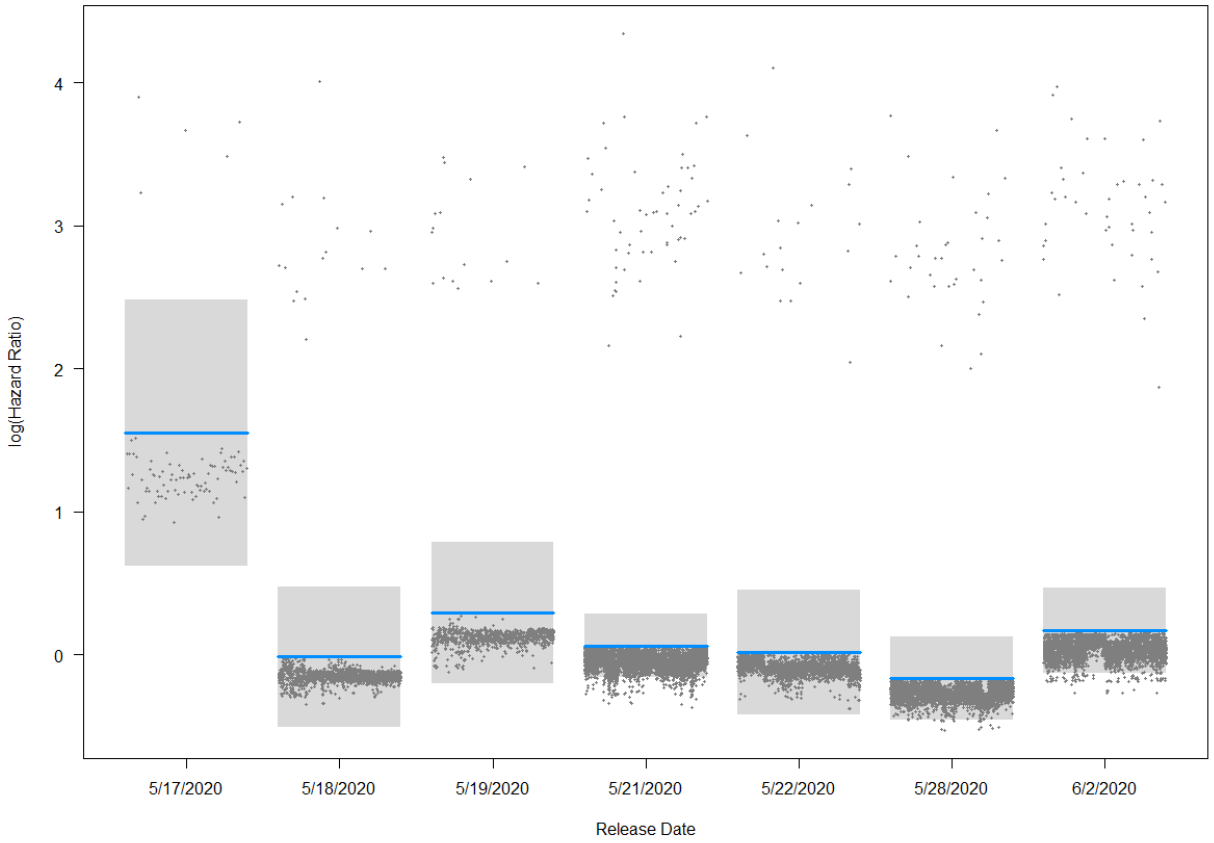

Figure 5–39. Results of the binomial GLM illustrating the relationship between release date and the probability of passage success for adult river herring at the Pawtucket Gatehouse.

5.8.1.2 E.L. Field Powerhouse Forebay

Similar to the results for the downstream adult river herring Pawtucket gatehouse model, release location and bypass flow failed to meet the assumptions of the Cox proportional hazard model for adult river herring downstream passage at the E.L. Field Powerhouse (Table 5-61). As a result, these covariates were excluded from consideration in the model. Inflow and release date were the only two covariates to pass the test of proportional hazards and were the only two covariates included in the model (Table 5-62). Results of the Cox proportional hazard model for downstream passage of adult river herring at the E.L. Field Powerhouse indicate a significant relationship between passage success and inflow, however this impact was marginal with inflow causing <1% decrease in the hazard ratio. Release date was significantly correlated with downstream adult river herring passage success at the E.L. Field Powerhouse, with an overall decrease in hazard ratio with later release dates (i.e., increased residence duration and lowered passage success during the latter part of the downstream migration window).

5.8.2 Adult American Shad – Downstream

A total of 8,219 Pawtucket Gatehouse and 30,028 E.L. Field Powerhouse forebay events were defined based on recorded detections of radio-tagged adult American shad during the 2020 study to evaluate the impact of operational parameters on passage success. The median event duration recorded for a radio-tagged shad was 54.8 seconds for individuals in the detection field of Station 06 immediately upstream of the Pawtucket Gatehouse and 2.1 minutes for individuals in the detection field of Station 08 covering the area immediately upstream of the E.L. Field intake structure.

5.8.2.1 Pawtucket Gatehouse

Results of the Cox proportional hazard model for the Pawtucket Gatehouse showed no significant relationships between event durations and operational parameters (Table 5-63; Table 5-64). Only release date exhibited a statistically significant correlation, with tagged adult American shad released on June 8 exhibiting significantly higher hazard ratios than tagged adult American shad released on June 6. Inflow was not included in this model as it was not independent of time and failed to meet the criteria of the model assumptions.

5.8.2.2 E.L. Field Powerhouse Forebay

Results of the Cox proportional hazards model for the E.L. Field Powerhouse indicated statistically significant relationships between passage success and inflow, release date, and

downstream bypass flow (Table 5-65). Inflow was determined to have a minor negative impact on downstream shad passage success at the E.L. Field Powerhouse, decreasing the likelihood of hazards occurring by approximately 1% as inflow increases (Table 5-66). On the contrary, release date and discharge through the downstream bypass exhibited positive correlations. The hazard probability for tagged adult American shad released on June 8 was higher than that for tagged adult American shad released on June 6. No variables were excluded from this model as they all met the time-independent assumptions of the Cox proportional hazards model.

5.8.3 Adult Alewives – Upstream

A total of 239 upstream foray events were defined based on recorded detections of adult alewives during the 2020 study to evaluate the impact of operational parameters on passage success. A description of the upstream magnitude and duration of those events is provided in Sections 5.4.3 for adult alewives.

Results of the Cox proportional hazard model were limited as the set of operations related parameters failed to meet the assumption they were independent of time and as a result were not included in the model (Table 5-67). The final adult alewife model assessed the hazards to passage success as a function of path selection (i.e., Pawtucket Dam fish ladder or the E.L. Field fish lift) and release date (Table 5-68). Results of the Cox proportional hazard model indicated a marginally significant relationship between path selection and hazard ratio in addition to a significant relationship between release date and hazard ratio. Based on these outputs, adult river herring utilizing the Pawtucket Dam fish ladder are less likely to experience passage failure than those using the E.L. Field fish lift. Foray attempts directed towards the E.L. Field fish lift increased the hazard (or probability of failure) by 62%. With regards to release date, adult alewives released during the beginning of the study were more likely to pass successfully than fish released during the latter part of the evaluation. No release date was found to negatively impact the hazard.

In an effort elucidate any existing correlations between passage success/failure or delay and the operational parameters available, a generalized additive model (GAM) with a Tweedie-distribution and generalized linear model (GLM) with a binomial distribution were built from the package '*mgcv*' in the Program R (R Core Team 2020). These model types allow for flexible parameterization of the error structure and offer an alternative method for exploring the relationships in question under a different suite of model assumptions.

GLMs were constructed as a means of understanding whether event success was correlated with turbine discharge, spill, release date, or path selection. Results of this model indicated a statistically significant negative correlation between passage successes and E.L. Field fish lift attempts with successful passage events occurring most frequently at the Pawtucket Dam fish ladder (Figure 5-40). This reaffirms the results of the Cox model, which suggests that adult alewives attempting to utilize the E.L. Field fish lift are more likely to incur a hazard (i.e., fail).

No statistically significant relationships were identified between upstream passage success and operational parameters (i.e., total bypass reach flow, spill flow, or inflow).

GAMs were built in an attempt to understand which covariates exhibited a significant impact on the duration of each event (i.e. which covariates are responsible for causing delay in upstream passage attempts for adult alewives). In addition to release date, turbine discharge, and route selection, event type (i.e., success/failure) was included in the GAM as a covariate to assess whether passage success or failure significantly impacted the duration of an event. Results of this model agreed with that of the GLM, suggesting event duration was negatively correlated with adult alewife attempts at the E.L. Field fish lift and positively correlated with passage success (i.e. adult alewives attempting to use the E.L. Field fish lift had longer event durations, but successful passage reduced event duration). In addition, results of the adult alewife GAM suggested that event durations are significantly and negatively correlated with increasing spill such that increasing spill decreases event durations. However, given that spill was not found to be a significant factor impacting passage success, it can be inferred that the shorter durations are the result of fish exiting the system during periods of high spill flow. This does not suggest that increasing spill will increase passage efficiency.

5.8.4 Adult American Shad – Upstream

A total of 202 upstream foray events were defined based on recorded detections of American shad during the 2020 study to evaluate the impact of operational parameters on passage success. Of those 202 events, 201 were identified as forays directed towards the E.L. Field fish lift and 1 was identified as a foray directed towards the Pawtucket Dam fish ladder. A description of the upstream magnitude and duration of those events is provided in Sections 5.5.3 for adult American shad.

A meaningful Cox proportional hazard model was unable to be built to represent upstream passage for adult American shad at Lowell. The full set of variables failed to meet the assumption that they are independent of time (Table 5-69). In lieu of that, a GAM with a Tweedie-distribution and GLM with a binomial distribution were assembled to evaluate upstream passage for adult American shad at Lowell.

GLMs were constructed as a means of understanding whether turbine discharge, spill, or event duration had statistically significant impacts on the probability of passage success (i.e., event = 1). Results of this model indicate a statistically significant positive correlation between passage successes and event duration with most successful passage events occurring after 1 hour (4000 seconds; Figure 5-41). No statistically significant relationships were identified between passage success and operational parameters (i.e., i.e., total bypass reach flow, spill flow, or inflow). Due to the limited observations of dual-tagged adult shad ascending the bypassed reach in an attempt to reach the Pawtucket Dam fish ladder, path selection was not included in this model.

GAMs were built in an attempt to understand which covariates exhibited a significant impact on the duration of each event (i.e. which covariates are responsible for causing delay in upstream passage attempts). In addition to turbine discharge and spill flow, event type (i.e., success/failure) was included in the GAM as a covariate to assess whether passage success or failure significantly impacted the duration of an event. Results of this model suggested statistically significant correlations between several covariate and event duration. Covariates with the heaviest influence on event duration were passage success (event = 1) and turbine discharge. In both instances, event duration was positively correlated, suggesting that shad exhibiting a longer event duration are more likely to successfully pass and that event duration increases with turbine discharge. With regard to spill flow, results of this model suggest that event durations are significantly and negatively correlated with increasing spill such that increasing spill decreases event durations (Figure 5-42). However, given that spill was not found to be a significant factor impacting passage success, it can be inferred that the shorter durations are the result of fish exiting the system during periods of high spill flow. This does not suggest that increasing spill will increase passage efficiency.

Table 5–69. Output of the Schoenfield residual test for time independence of covariates in Cox proportional hazard model for adult American shad upstream passage events.

5.9 Manual Tracking

In addition to the continuous monitoring provided by the set of stationary receivers installed throughout the Project area for the duration from early May through June 2020, a total of 99 manual detections representing 67 individuals (20 alewives and 47 American shad) were recorded between May 29 and July 2. Appendix E contains a listing of manual detections identified to the nearest 0.25 mile and classified as "Transit" for tagged fish which were subsequently detected at stationary receivers downstream of their manually determined position or "Final" for tagged alosines which were detected within the section of river bounded by the receiver station(s) at which their final stationary detection was recorded (e.g., manual detection of a fish immediately upstream of Essex Dam with stationary detections at Stations 26 and 27 would be classified as "Final" for that reach). Manual detections classified as "Transit" were predominantly recorded for individuals in the upper sections of the study area (i.e., upstream of Station 04 (17 observations) or between Stations 04 and 05 (9 observations)). Manual detections classified as "Final" were mostly recorded in the reach between Stations 26 and 27 which represented the bottom of the study reach at Essex Dam (44 observations). Manual detections were classified as "Final" for an additional 12 observations recorded upstream of Station 04 for individuals which failed to approach Pawtucket Dam.

6 Summary

An evaluation of the upstream and downstream passage effectiveness for adult alewives and American shad was conducted in support of the FERC relicensing of the Lowell Hydroelectric Project. Fish passage effectiveness was evaluated using telemetry during the 2020 spring passage season (May through June). Merrimack River conditions during the spring 2020 passage assessment were considered as normal or low for the majority of May and low for most of the month of June. The E.L. Field fish passage facilities (i.e., upstream fish lift and downstream fish bypass) were operated throughout the study period and those turbine units were in operation for the duration of the study period. Two major spill events, associated with increases in river flows, occurred during the early portion of the monitoring period (May 7 and May 18). Outside of those two periods of increased discharge, flows through the bypassed reach during the 2020 monitoring period were comprised of the ~500 cfs of water constituting the attraction and conveyance flow associated with the Pawtucket Dam fish ladder as well as incidental spill flow passing over the spillway. Incidental spill flows in excess of 500 cfs were present until May 21 after which incidental spill was reduced to near zero through the month of June. Flows to the downstream canal system were limited during both months as Boott suspended operation of the generating units in that system prior to the onset of the study due to overriding safety concerns.

6.1 Adult Alewife

A total of 504 adult alewives were radio and/or PIT-tagged over a range of dates from May 7 through June 2, 2020. Of that total, 354 (150 dual-tagged and 204 PIT-tagged) were tagged and released at the Lawrence Project (FERC No. 2800) fish lift facility and were evaluated for upstream passage at Lowell. The remaining 150 radio-tagged adult alewives were sourced from either the fish passage facility at Lawrence or the upstream fish ladder at Amoskeag Dam in

Manchester, NH (FERC No. 1893) and were released upstream of Lowell at the Tyngsborough Riverfront Park for the evaluation of downstream passage. An additional set of radio-tagged adult alewives released as part of a concurrent fish passage study on the Nashua River were also monitored for downstream passage at Lowell. Of the dual-tagged adult alewives released downstream of the Project, 85% were determined to have approached Lowell and were available to assess passage effectiveness of either E.L. Field powerhouse fish lift or the Pawtucket Dam fish ladder. Of the 150 radio-tagged adult alewives released upstream of Lowell, 83% approached the Pawtucket Dam and were available to evaluate downstream passage at the Project. The downstream passage analysis for adult alewives at Lowell was supplemented with information from an additional 93 individuals which approached Pawtucket Dam following release in the Nashua River.

Releases of dual-tagged alewives downstream of the Project occurred over six dates between May 7 and May 19, 2020 and individuals were observed approaching the Lowell Project as early as the initial date of release through May 23. The duration of time for fish to move upstream from the release location at Lawrence to Lowell was around one day for most dual-tagged adult alewives (median = 19.6 hours; 75th percentile = 28.6 hours). Following arrival downstream of the Project, 95% of dual-tagged adult alewives made at least one foray upstream towards either the fish lift or ladder. When examined by structure 64% of dual-tagged alewives made at least one foray in the direction of the fish lift, 67% in the direction of the fish ladder, and 39% in the direction of the fish lift and fish ladder.

The 82 dual-tagged adult alewives determined to have approached the E.L. Field fish lift produced a combined total of 134 unique foray events. Approximately 66% of the set of upstream foray events towards the E.L. Field fish lift resulted in detection of the dual-tagged alewife at the lift entrance and the median duration of time to locate the fish lift entrance was 0.7 hours. Fish lift entrances were recorded over a range of dates from May 8 through May 30 and peaked during mid-May. Upstream effectiveness of the E.L. Field fish lift was assessed using a CJS model and for an individual adult alewife which entered the tailrace channel estimated the probability of locating the entrance (i.e., the nearfield attraction) at 83.3%. The overall effectiveness of the E.L. Field fish lift for adult alewife passage during 2020 was estimated at 43.9% (75% CI = 39.3-51.4%). Following upstream passage at the lift, dual-tagged adult alewives proceed quickly upstream to the downstream face of the Pawtucket Gatehouse (median duration = 0.7 hours). The median duration of time for dual-tagged adult alewives to pass the Pawtucket Gatehouse was 25.7 hours.

A total of 86 adult alewives made at least one foray in the direction of the Pawtucket Dam fish ladder during their time at large in the Project area. Of the 105 total forays towards the fish ladder, 51% resulted in at least one detection at the ladder entrance and the median duration of time to locate the entrance once an individual had arrived at the upper end of the bypassed reach was 4.0 hours. Fish lift entrances were recorded for dual-tagged adult alewives over a range of dates from May 7 through May 23 and peaked during mid-May. Additional observations of PIT-tag only adult alewife entrances into the fish ladder occurred over a comparable range of dates (May 9 to May 27). Upstream effectiveness of the Pawtucket Dam

fish ladder was assessed using a CJS model and for an individual adult alewife which ascended to the upper end of the bypassed reach the probability of locating the entrance (i.e., the nearfield attraction) was 93.0%. The overall effectiveness of the Pawtucket Dam fish ladder for adult alewife passage during 2020 was estimated at 75.6% (75% CI = 69.2-82.2%). The median duration of time from initial detection at the fish ladder entrance until exit at the top of the structure for dual-tagged adult alewives was 2.9 hours (lower leg median duration = 2.1 hours; upper leg median duration = 1.1 hours). Supplemental data collected for the PIT-tag only adult alewives which entered the Pawtucket Dam fish ladder corresponded with observations for the dual-tagged fish (median ladder passage duration = 3.8 hours; lower leg passage = 1.6 hours; upper leg passage = 1.2 hours).

Outmigration of radio-tagged adult alewives was observed over a range of dates from May 21 to June 17 with a peak number of events occurring between June 3 and 6. The median upstream residence time prior to downstream passage was 1.8 days with 78% of those individuals passing downstream within 96 hours of arrival. The majority of individuals passed downstream of Lowell via the E.L. Field turbine units (47% of radio-tagged alewives) or utilized the downstream bypass (45% of radio-tagged alewives). Downstream passage survival was calculated as the joint probability of the three reach-specific survival estimates which encompasses the full section of the Merrimack River from Lowell downstream to Lawrence and resulted in an estimated downstream passage survival for adult alewives at Lowell of 80.1% (75% CI = 76.7%-83.6%). This estimate of downstream passage survival for adult alewives at Lowell includes background mortality (i.e., natural mortality) for the species in the downstream reach, along with any tagging-related mortalities or tag regurgitations. As a result, this estimate should be viewed as a minimum estimate of total project survival (i.e., due solely to project effects) for adult alewives at the Project. Downstream passage survival for adult alewives utilizing the E.L. Field turbine units and downstream bypass facility was 73.9% (75% CI = 68.8%-79.1%) and 87.8% (75% CI = 81.8%-91.5%), respectively.

6.2 Adult American Shad

A total of 534 adult American shad were radio and/or PIT-tagged over a range of dates from May 16 through June 8, 2020. Of that total, 384 (180 dual-tagged and 204 PIT-tagged) were tagged and released at the Lawrence fish lift facility and were evaluated for upstream passage at Lowell. The remaining 150 radio-tagged adult American shad were collected from the fish passage facility at Lawrence and were released upstream of Lowell at the Tyngsborough Riverfront Park for the evaluation of downstream passage. Of the dual-tagged adult American shad released downstream of the Project, 40% were determined to have approached Lowell and were available to assess passage effectiveness of either E.L. Field powerhouse fish lift or the Pawtucket Dam fish ladder. An additional 47% of the dual-tagged shad exhibited upstream movement following tagging and release at Lawrence but did not move the full length of the Merrimack River reach between the two Projects. Of the 150 radio-tagged adult shad released upstream of Lowell, 79% approached the Pawtucket Dam and were available to evaluate downstream passage at the Project.

Releases of dual-tagged American shad downstream of the Project occurred over five dates between May 16 and May 27, 2020 and individuals were observed approaching the Lowell Project between May 17 and June 6. The median duration of time for shad to move upstream from the release location at Lawrence to Lowell was 64.5 hours (2.7 days). Following arrival downstream of the Project, 63% of dual-tagged adult American shad made at least one foray upstream towards either the fish lift or ladder. The vast majority those shad made one or more forays in the direction of the fish lift. Only a single dual-tagged shad was determined to have initiated an upstream ascent into the bypassed reach and in the direction of the fish ladder.

The 43 dual-tagged adult American shad determined to have approached the E.L. Field fish lift produced a combined total of 201 unique foray events. Approximately 37% of the set of upstream foray events towards the E.L. Field fish lift resulted in detection of the dual-tagged shad at the lift entrance and the median duration of time to locate the fish lift entrance was 1.1 hours. Fish lift entrances were recorded over a range of dates from May 18 through June 15 and peaked during late-May. Upstream effectiveness of the E.L. Field fish lift was assessed using a CJS model and for an individual adult shad which entered the tailrace channel estimated the probability of locating the entrance (i.e., the nearfield attraction) at 67.4%. The overall effectiveness of the E.L. Field fish lift for adult American shad passage during 2020 was estimated at 30.4% (75% CI = 22.1-39.5%). Following upstream passage at the lift, dual-tagged adult shad proceed quickly upstream to the downstream face of the Pawtucket Gatehouse (median duration = 0.8 hours). The median duration of time for dual-tagged adult shad to pass the Pawtucket Gatehouse was 5.4 days.

Upstream movement of dual-tagged shad within the Lowell bypassed reach was limited to a single individual which was detected only at the lowermost receiver within that reach. There were no detections of any dual-tagged adult American shad at the Pawtucket Dam fish ladder during the 2020 study. Similarly, detections of PIT-tagged adult shad were also very limited during the 2020 study period. Of the 204 PIT-tagged adult shad released at Lawrence during the onset of the study only two individuals were determined to have entered the fish ladder.

Outmigration of radio-tagged adult American shad was observed over a range of dates from June 4 to June 27 with a peak number of events occurring on or before June 15. The median upstream residence time prior to downstream passage was 3.9 days with 51% of individuals passing downstream in less than 96 hours after their arrival. The majority of individuals passed downstream of Lowell via the E.L. Field turbine units (26%), the downstream bypass (28%) or utilized the bypassed reach (38% of radio-tagged shad). Downstream passage survival was calculated as the joint probability of the three reach-specific survival estimates which encompasses the full section of the Merrimack River from Lowell downstream to Lawrence and resulted in an estimated downstream passage survival for adult shad at Lowell of 70.0% (75% CI = 64.5%-74.6%). This estimate of downstream passage survival for adult shad at Lowell includes background mortality (i.e., natural mortality) for the species in the downstream reach, along with any tagging-related mortalities or tag regurgitations. As a result, this estimate should be viewed as a minimum estimate of total project survival (i.e., due solely to project effects) for adult American shad at the Project. Downstream passage survival for adult American shad

utilizing the E.L. Field turbine units, downstream bypass facility or spill was 35.5% (75% CI = 25.8%-45.2%), 82.6% (75% CI = 75.7%-90.9%), and 89.2% (75% CI = 82.6%-93.8%), respectively.

7 Variances from FERC-Approved Study Plan

The timing of this field study (April – June 2020) coincided with the rapid onset of the COVID-19 pandemic throughout the United States and during the course of this evaluation both the States of New Hampshire and Massachusetts were operating under a "stay-at-home" order. Every effort was made to conduct this evaluation as described in the FERC-approved RSP while still maintaining the health and safety of all Normandeau project staff and Boott operations staff.

Variances from the RSP included:

- Monitoring Station M20 was described in the RSP as a PIT-reader to be installed at the hopper discharge of the E.L. Field fish lift. Range testing conducted following installation of this antenna indicated significant background interference at that location reducing the read range of the antenna to near zero. As a result that unit was moved further upstream to allow for a pair of readers to provide coverage of the fish lift exit flume.

- Monitoring Stations C3 and C7 were described in the RSP as PIT-readers. Following initial site reconnaissance it was determined by Normandeau field staff that the intended detection area was not suitable for a PIT antenna. As a result those two locations were instead monitored using a Sigma-Eight Orion radio telemetry receiver. This change in equipment was noted during the March 2020 ISR meeting held in Lowell, MA.

- As Boott was not operating the downtown canal units due to safety concerns, the 100 radio-tagged adult alewife and shad (50 each) proposed in the RSP for release into the downtown canal system to assess outmigration through those facilities were instead placed in the river upstream of Lowell to increase the sample size for the downstream passage assessment. Boott consulted with both USFWS and NHFGD prior to making this modification.

- Due to uncertainty in returns of adult river herring at Lawrence towards the tail end of the monitoring period, Boott relied on the use of 70 adult alewives collected at the Amoskeag trap and truck facility in Manchester, NH. These individuals were radio-tagged and the released into the river upstream of Lowell to evaluate downstream passage of that species. Boott consulted with both USFWS and NHFGD prior to making this modification.

- In their SPD and based on resource agency comments, FERC recommended placement of an additional stationary receiver along the eastern wall of the E.L. Field tailrace. Boott and Normandeau staff evaluated the eastern tailrace wall during the site

installation process and access to that reach was deemed unsafe. The study proceeded with a single tailrace receiver which operated without issue for the duration of the study period.

- In their SPD, FERC recommended fish be released at a point further upstream to reduce the potential for fallback downstream of Lawrence immediately following tagging and release. Adult alosines collected for upstream passage from the Lawrence fish lift were released directly into the exit flume of that facility following tagging. This change was made due to the lack of early season tank truck assistance to move American shad upstream as well as the closure of the public boat access upstream of Lawrence by the City due to the ongoing COVID situation.

- The evaluation of the E.L. Field fish lift as part of the spring 2020 adult alosine passage evaluation was conducted under the same tailrace channel geometry as previous evaluations. As discussed during consultation with the resource agencies prior to the 2020 study, Boott could not guarantee that the planned tailrace ledge modifications could be completed in time to avoid interference with fish lift operations and this study.

Appendix B. Responses to September 30, 2020 Revised ISR meeting comments.

Comment No.	Agency	Comment	Response
1	USFWS	In Section 5.4.6 (Upstream Passage Effectiveness – Lowell Fish Ladder) please better identify the success rate corresponding with passage of adult river herring through the weir section of the bypass reach.	Clarifying language has been added to Section 5.4.6 of the final report.
2	MDMF	For circle plots showing the hourly distributions of arrival or passage times can you confirm that source data for those plots are based on individual events and are not the sum or all detections (which may skew results towards one or more hours based on continued detection of an individual(s)).	Circle plots in the final report have been reviewed and are based on individual events, not the sum of all detections.
3	FERC	Will the updated revised study report contain CJS model estimates of downstream passage survival by passage route?	Sections 5.6.4 and 5.7.4 contain route-specific downstream passage survival estimates for adult river herring and American shad.
4	MDFW	Can a section be added which provides a comparison of downstream passage metrics for adult river herring originating at Lawrence versus those originating at Amoskeag?	Appendix F has a summary of passage metrics for adult river herring released upstream of Lowell at Tyngsborough and originating at either Lawrence or Amoskeag.

Appendix C. Reported hourly operations information for the Lowell Project for the duration of the 2020 spring telemetry study.

Report Appendix C available as Microsoft Excel data listing.

Appendix D. Project inflow and discharge by potential passage route at the time of downstream passage for radio-tagged adult alosines at Lowell.

Adult Alewives:

Appendix F. Tyngsborough adult river herring releases – comparison of individuals originating at Lawrence vs. Amoskeag Dam.

Adult river herring radio-tagged and released into the mainstem Merrimack River in Tyngsborough for the assessment of downstream passage at Lowell originated at Lawrence (May 21 and May 22 releases; n = 80 fish) and at Amoskeag Dam (May 28 and June 2 releases; n = 70 fish). Table F-1 provides a comparison of the range of values for movement indices evaluated during this study and between the two groups. Based on comparison of the quartile values, observations for most metrics did not appear to differ between the two groups. The approach duration (i.e., time to pass from Station 04 to approach at the dam (Station 05)) was longer for individuals collected at Lawrence. Fish collected at the fish lift at Lawrence were likely pre-spawn individuals and may have moved upstream following release versus the fish collected at Amoskeag which showed a more directed downstream approach following their release at Tyngsborough. Residence in the Lowell project area did not appear to vary for the release groups originating at Lawrence or Amoskeag Dams. Similarly, the period of time to move downstream from Lowell to Lawrence did not vary greatly among the defined downstream reaches based on the quartile ranges for passage from Lowell to Station 25, Station 25 to Station 26 and Station 26 to detection at Lawrence. With regards to passage at Lowell, the majority of radio-tagged adult river herring originating at Lawrence and Amoskeag passing downstream did so via the turbines or downstream bypass facility (Figure F-1).

Table F-1. Minimum, maximum, and quartile values for the suite of movement metrics assessed for radio-tagged adult river herring originating at Lawrence and Amoskeag and released upstream of Lowell in Tyngsborough.

Movement Metric	Origin	Value				
		Min	Max	P25	Median	P75
Approach Duration (hrs)	Lawrence	6.7	323.6	135.2	179.1	234.1
	Amoskeag	11.5	155.1	27.6	33.6	40.5
Upstream Residence Duration (hrs)	Lawrence	0.8	210.1	25	44.7	88.5
	Amoskeag	0.7	181.7	26.1	49.4	90.2
Pawtucket Gatehouse Passage (hrs)	Lawrence	0	99.3	0.2	0.5	6.1
	Amoskeag	0	94.2	0.6	2.6	20.8
Northern Canal Residence (hrs)	Lawrence	0.2	38.2	0.3	0.4	2.2
	Amoskeag	0.2	42.3	0.4	0.7	5.6
Downstream Travel: Lowell to Station 25 (hrs)	Lawrence	1.1	50.8	3.4	5.3	11.6
	Amoskeag	1.5	28.5	2.9	4.8	7.6
Downstream Travel: Station 25 to Station 26 (hrs)	Lawrence	1.7	4.5	1.9	2.2	2.9
	Amoskeag	1.9	16.5	2.4	2.8	3.7
Downstream Travel: Station 26 to Station 27 (hrs)	Lawrence	2.6	138.9	10.7	18.8	21.0
	Amoskeag	4.1	68.2	17.6	19.4	21.1

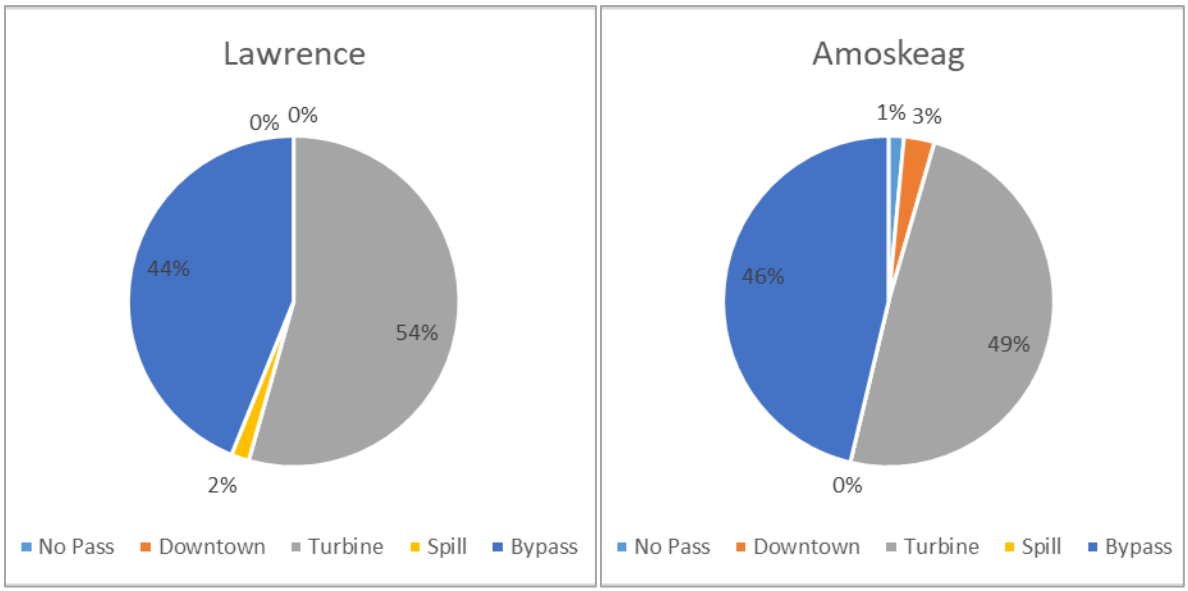

Figure F-1. Downstream passage route distribution observed at Lowell for radio-tagged adult river herring originating at Lawrence (left panel) and Amoskeag (right panel) and released upstream of Lowell in Tyngsborough.

1 Introduction

A survey of the resident fish community was conducted in support of the relicensing for the Lowell Hydroelectric Project (Lowell or Project), Federal Energy Regulatory Commission (FERC) No. 2790, as identified in the Revised Study Plan (RSP) submitted by Boott Hydropower, LLC (Boott) on January 28, 2019. The approach and methodology described in the RSP for the fish community study was approved by FERC in its Study Plan Determination letter dated March 13, 2019.

In accordance with 18 C.F.R. § 5.15(c), Boott filed their Initial Study Report (ISR) with FERC on February 25, 2020. As described in the ISR, data analyses were in progress and scheduled for completion during 2020. On June 12, 2020 FERC issued a Revised Process Plan and Schedule and Determination on Requests for Study Modifications for the Lowell Hydroelectric Project (Revised PPS). In accordance with the Revised PPS, Boott filed their Revised ISR with FERC on September 30, 2020, which contained a full report for the Fish Assemblage Study. Boott held a revised ISR meeting on October 15, 2020 and a summary of the study results was presented to representatives from FERC, U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), Massachusetts Division of Fisheries and Wildlife (MADFW), Massachusetts Division of Marine Fisheries (MDMF), and the New Hampshire Fish and Game Department (NHFGD). No significant comments on the Fish Assemblage Study were received.

This final technical report provides a description of the objectives, methodologies and results of the 2019 field sampling intended to describe the fish community within the Lowell Project area.

2 Objectives

The goal of this study was to characterize the fish assemblage in areas affected by the Lowell Project, specifically the impoundment and bypassed reach.

Specific objectives included:

- Field sampling to describe the fish assemblage structure, distribution, and abundance within the Project affected area along spatial and temporal gradients; and
- A comparison of historical records of fish species occurrence in the Project area to results of this study.

3 Project Description and Study Area

The Lowell Project is located at River Mile (RM) 41 on the Merrimack River in the City of Lowell in Middlesex County, Massachusetts, with an impoundment extending approximately 23 miles upstream into Hillsborough County, New Hampshire. The existing Lowell Project consists of: (1) a 1,093-foot-long, 15-foot-high masonry gravity dam (Pawtucket dam) that includes a 982.5-foot-long spillway with a crest elevation of 87.2 feet National Geodetic Vertical Datum 1929 (NGVD 29) topped by 5-foot-high pneumatically-operated crest gates deployed in five independently-operable zones; (2) a 720-acre impoundment with a normal maximum water

surface elevation of 92.2 feet NGVD 29; (3) a 5.5-mile-long canal system which includes several small dams and gatehouses; (4) a powerhouse (E.L. Field) which uses water from the Northern Canal and contains two turbine-generator units with a total installed capacity of 15.0 megawatts (MW); (5) a 440-foot-long tailrace channel; (6) four powerhouses (Assets, Bridge Street, Hamilton, and John Street) housed in nineteenth century mill buildings along the Northern and Pawtucket Canal System containing 15 turbine-generator units with a total installed capacity of approximately 5.1 MW; (7) a 4.5-mile long, 13.8-kilovolt transmission line connecting the powerhouses to the regional distribution grid; (8) upstream and downstream fish passage facilities including a fish elevator and downstream fish bypass at the E.L. Field powerhouse, and a vertical-slot fish ladder at the Pawtucket dam; and (9) appurtenant facilities. At the normal pond elevation of 92.2 feet NGVD 1929 (crest of the pneumatic flashboards), the surface area of the impoundment encompasses an area of approximately 720 acres. The gross storage capacity between the normal surface elevation of 92.2 feet and the minimum pond level of 87.2 feet is approximately 3,600 acre-feet. The Project operates essentially in a run-of-river (ROR) mode using automatic pond level control, and has no usable storage capacity.

The study area for this fish community survey included the mainstem Merrimack River from the Pawtucket Dam to the upper extent of the Project's impoundment located approximately 23 river miles upstream, and the Project's 0.7-mile-long bypassed reach.

4 Methods

4.1 Lowell Impoundment

The 23-mile-long (37 kilometer) impoundment was stratified based on mesohabitat characteristics. Each stratum was delineated in 547-yard (500-meter) segments using Aeronautical Reconnaissance Coverage Geographic Information System (ArcGIS). Sampling locations were randomly selected and weighted proportional to mesohabitat type frequency (e.g., if 50 percent of a particular geographic reach was shallow, riffle habitat, then 50 percent of the total number of sampling locations for that geographic reach were randomly placed within that habitat type). As long as habitat was accessible, efforts were made to ensure that a minimum of three sampling locations were placed within each strata (i.e., habitat type). A total of twelve, 547-yard (500-meter) segments were randomly selected within the reach so that approximately 16% of the impoundment was sampled. The stratified-random site selection process was repeated for each of three seasonal surveys (spring, summer, and fall).

Following selection of the twelve, 500-meter sample units, boat electrofish sampling took place during the nighttime hours (as defined by daily sunset/sunrise times). A single bank (east or west) was randomly selected for each sample unit. Prior to the start of sampling, settings on the electrofishing unit were adjusted by a trained crew member to ensure that approximately 4.0 amps of pulsed DC current was being generated. After recording the start time, boat electrofish sampling consisted of a single shoreline pass starting at the upstream end of each 500m transect and proceeded downstream. Effort was made by the boat driver to follow the shoreline contour and probe the sampling anodes into habitat areas (i.e., overhanging vegetation, submerged aquatic vegetation, woody debris, etc.). The boat driver maintained the

boat in near-shore littoral habitat (< 10-feet deep) where the sampling field would be most effective. A pair of netters stood on the bow of the sampling vessel and placed all stunned fish into an onboard live well for processing. Once the sample transect was finished, the driver recorded the completion time and duration of the sampling effort.

An experimental gill net was set concurrent with boat electrofishing in each 500-m sample unit. Gill nets were fished within all sample units containing adequate water depths and flow conditions to allow for proper performance of the nets, specifically deep and mid-channel microhabitats. Experimental gillnets were eight feet deep and were constructed of four 25-ft panels of increasing mesh size (1.0, 2.0, 3.0, and 4.0-inch stretch mesh). Gillnets were set during nighttime hours (as defined by daily sunset/sunrise times) when fish species are most susceptible to the gear due to the reduced visual avoidance. Gillnets were deployed perpendicular to the shoreline in areas where water depths were greater than the net height and capture area was maximized. Nets were set and fished for an approximate four-hour period prior to retrieval to minimize netting mortality. Net set coordinates and the date and time of each set and pull were recorded.

To supplement experimental gill net sampling in deeper habitats (> 10 ft) where electrofishing is not effective and small fish and eels are not susceptible to gillnets, a pair of standard minnow traps were deployed. The traps were 2.5 feet long galvanized wire mesh (0.25 square inch) cylinders with two entry fykes. Traps were baited and anchored to remain on station for the duration of their soak time. For each sample unit, two traps were fished simultaneously with gillnets for an approximate four-hour period. Trap set coordinates and the date and time of each set and pull were recorded.

All fish collected from the impoundment were identified to the lowest possible taxonomic classification (preferably to species), enumerated, measured to total length (to the nearest mm), and weighed (to the nearest g). If large numbers of small fish (i.e., YOY or small cyprinid species) were captured, length and weight information was collected from the first 25 individuals within the sample and the remaining individuals were grouped, enumerated, and batch weighed.

For each 500-m sample unit, the sampling crews visually evaluated habitat within the reach. The dominant substrate (organics, sand/silt/clay, cobble/gravel, boulder, or ledge), proportion of transect with submerged aquatic vegetation (i.e., 0-25%, 5-50%, 50-75%, or 75-100%), and the proportion of transect with overhanging vegetative cover (i.e., 0-25%, 5-50%, 50-75%, or 75-100%) was recorded. To get a sense of relative water depth for the Merrimack River at each sampling transect, a series of nine measurements were collected. River depths were recorded at the quarter points (i.e., 25, 50, and 75%) of three cross sections placed at the upstream extent, downstream extent, and midpoint of each sample unit. A representative water velocity (ft/s) was recorded at the midpoint of the middle cross-section of each habitat unit. Following documentation of sample unit habitat and characteristics, a representative water quality measurement was collected at approximately one meter of depth. Water temperature (^{o}C), dissolved oxygen (mg/L) conductivity (µs/cm), pH, and turbidity (ntu) were recorded.

4.2 Lowell Bypassed Reach

Delineation of sample units was scaled for the shorter, less accessible bypassed reach. Each stratum was delineated in 55-yard (50-meter) segments using ArcGIS. Sampling locations were randomly selected and weighted proportional to mesohabitat type frequency. As long as habitat was available, effort was made to ensure that at least one sampling location was placed within each strata (i.e., habitat type) within the bypassed reach. A total of three segments were randomly selected within the bypassed reach during each of three seasonal surveys (spring, summer, fall). Due to safety and gear limitations, sampling was not conducted in (1) the reach from the Pawtucket Dam downstream to the School Street Bridge, and (2) the lowermost section of the bypass channel downstream of the Northern Canal surge gate. Sampling was limited to periods of minimum flow in the bypassed reach.

Backpack electrofish sampling was conducted within the Lowell bypassed reach. Halltech Aquatic Research Model HT2000B/MK5, battery-powered backpack electrofishers with ring probes and rattail cathodes were used to sample within the bypassed reach. Sampling was conducted by anchoring a fine mesh seine at the downstream end of a 50-m sample unit. A pair of backpack electrofishing units and four technicians moved in a downstream direction towards the seine while actively netting stunned individuals and kicking the substrate to drive additional stunned individuals towards the collection net. Backpack electrofish sampling was conducted during daylight hours. The backpack units were set at 550 volts at 100 Hertz (Hz). The start time, end time and duration of sampling were recorded for each sample unit. Specifics related to habitat and effort were the same as described above for impoundment sampling.

5 Results

5.1 Lowell Impoundment

5.1.1 Habitat Evaluation and Sample Unit Selection

A pair of biologists boated the stretch of the Merrimack River from the Pawtucket Dam upstream 23.0 miles to the uppermost extent of the Project area on May 18, 2019. Changes in mesohabitat type were visually identified and their locations recorded. Following importation of those habitat break points into ArcGIS, the 23.0 miles of the Merrimack River upstream of Lowell impoundment was subdivided into a total of 74 547-yard (500-meter) segments. The majority of those (78%) were classified as impoundment habitat. Lesser amounts of the overall reach were classified as run (7%) and pool (15%). The spatial distribution of mesohabitat types and 500-m segments for the 23.0 miles upstream of Lowell is provided in Appendix A.

Table 5-1 provides a listing of the habitat units upstream of the Pawtucket Dam that were randomly selected for sampling during the spring, summer, and fall periods of 2019. A total of twelve, 500-m segments were selected per season. During the spring season, a total of six impoundment, three run and three pool habitat units were sampled. River conditions (i.e., water depth) prevented effective sampling within some of the run habitat at the uppermost end of the Project area during the summer and fall sampling periods. As a result, seven impoundment, two run, and three pool habitat units were sampled during those seasons.

5.1.2 Sampling Effort

Fish community data were collected from a total of 36, 500-m sample units during the spring, summer, and fall of 2019 (12 sites per season). Effort expended at a sample unit during each of the three seasons consisted of (1) a 500-m shoreline boat electrofish sample, (2) a four hour experimental gill net set, and (3) a four hour baited minnow trap set. Fish community sampling in the Lowell impoundment occurred on June 24-26 (spring), August 19-21 (summer) and October 28-30 (fall). Tables 5-2 through 5-4 provide a summary of boat electrofish, gill net and minnow trap sampling in the Lowell impoundment. Impoundment sample units selected by season are presented visually in Appendix A.

5.1.3 Species Richness and Composition

A total of 1,847 individuals representing twenty-two fish species were collected from the Lowell impoundment during 2019 when all sampling seasons and sample units are considered (Table 5-5). The total impoundment catch represents all individuals collected and identified during boat electrofish and gill net sampling. There were no fish collected via minnow trap during the 2019 survey. Table 5-6 provides a summary of the impoundment community composition by season (electrofish and gill net). Spottail shiner (23.0%), redbreast sunfish (20.5%) and smallmouth bass (12.3%) were the three most numerically abundant species within the Lowell impoundment during the 2019 sampling. When examined by species, spottail shiner were most abundant during the spring (27.6% of seasonal catch) and fall (33.9% of seasonal catch) whereas redbreast sunfish were most abundant during the summer period (27.1% of seasonal catch).

Total catch and community composition from sampling units upstream of Pawtucket Dam and classified as impoundment, pool and run mesohabitat types are presented in Table 5-7. Centrarchid species were the most abundant within impoundment habitat with redbreast sunfish (24.2%), pumpkinseed (14.2%), and smallmouth bass (12.5%) representing the three most abundantly sampled species. Spottail shiner were the most abundantly sampled fish species in the pool (28.4%) and run (46.3%) habitat areas.

The majority of catch in the impoundment was observed during boat electrofishing efforts (Table 5-8). A total of 1,792 individuals representing 20 fish species were collected. Spottail shiner, redbreast sunfish, and smallmouth bass were the most frequently observed species within the impoundment electrofish catch. Total boat electrofish catch within the impoundment was fairly even across seasons (high of 677 individuals during the summer to a low of 543 individuals during the fall). A total of 55 individuals representing 15 species were recorded during gill net sampling in the Lowell impoundment. Yellow bullhead was the most frequently encountered species during gill net sampling and the majority of catch was recorded during the summer season.

5.1.4 Relative Abundance

Relative abundance, the number of fish captured with known sampling effort and indexed as catch per unit of effort (CPUE), was calculated on a species-specific basis. CPUE values were standardized to a fixed unit of time or distance using the following equations:

For time (i.e., fish per hour): CPUE for taxon j in sample i = (catch ji / duration i) * 60 min

Where: duration is expressed in minutes

For distance (i.e., fish per 100 m): CPUE for taxon j in sample i = (catch ji / length i) * 100m

Where: length is expressed in meters

Prior to the calculation of any CPUE values the data set was "zero filled" for each fish species, such that each species collected in the study was represented in every sample. CPUE values were calculated for each fish species by season and gear.

Catch rates were highest for spottail shiner, redbreast sunfish and smallmouth bass captured by boat electrofish sampling in the 23.0 mile reach upstream of Pawtucket Dam during the 2019 sampling (Table 5-9). Values for fish per unit of effort were highest for spottail shiner and smallmouth bass during the spring sampling event, redbreast sunfish and spottail shiner during the summer sampling event and fallfish and alewife during the fall sampling event. Table 5-10 provides CPUE rates for fish collected during gill net sampling in the upstream reach during 2019. The CPUE rate for yellow bullhead was the highest for fish collected in the experimental gill nets. A listing of CPUE rates for all species by season and mesohabitat type is provided in Appendix B.

5.1.5 Biocharacteristics

Length frequency distributions for fish species where 25 or more individuals were collected and measured during the impoundment sampling are presented in Appendix E. The observed range for fish sizes recorded for species observed in both the boat electrofish and gill net catch from the Lowell impoundment fall within the expected bounds for those species in the northeastern U.S. (Table 5-11). A full listing of catch data is provided in Appendix F.

5.1.6 Habitat and Water Quality Characteristics

Tables 5-12 and 5-13 provide summaries of habitat and water quality information recorded for each of the 36, 500-m sample units surveyed during the spring, summer and fall seasons. Dominant substrate, presence of submerged aquatic vegetation (SAV), and presence of general cover were consistent among all sample units regardless of mesohabitat classification (i.e., pool, run or impoundment). Sampled areas upstream of Pawtucket Dam were characterized by sand-silt-clay sediments, presence of SAV over 0-25% of the sample area and the presence of general cover over 0-25% of the sample area. Mean water depth (as sampled at quarter points of the river channel at the upper, middle, and lower points of each transect) trended towards shallower at the upper end of the reach upstream of Pawtucket Dam in areas classified as pool and run and deeper at the lower end in areas classified as impoundment.

Water temperature was relatively consistent among sample units with a ± 1-2^{o}C range in values within each season. The average Merrimack River water temperature was 21.5^{o}C during the spring sampling, 25.6^{o}C during the summer sampling, and 10.8^{o}C during the fall sampling. Dissolved oxygen was measured at 8.1 mg/L or greater at all stations upstream of Pawtucket

Dam regardless of season. Conductivity averaged 114 µs/cm during the spring sampling, 181 µs/cm during the summer sampling, and 117 µs/cm during the fall sampling. In general, conductivity increased with proximity to the Pawtucket Dam. River pH was consistent across seasons ranging from 6.5-7.5. The average turbidity reading was higher during the spring sampling (2.6 NTU) than was observed during the summer or fall periods (1.8 and 1.6 NTUs, respectively).

Table 5–1. Sample unit habitat type and location for the spring, summer and fall Lowell impoundment fish community survey

5.2 Lowell Bypassed Reach

5.2.1 Habitat Evaluation and Sample Unit Selection

Changes in general habitat types within the Lowell bypassed reach were visually identified and marked in ArcGIS. The approximately 0.75 mile reach downstream of Pawtucket Dam was subdivided into a total of 23, 55-yard (50-meter) segments. The bypassed reach was subdivided into habitat classifications associated with the upper chute (i.e., the area between Pawtucket Dam and School Street Bridge), pooled section immediately downstream of the School Street Bridge, ledge channel area in the vicinity of the University Avenue Bridge, and the lower bypassed reach downstream of the power canal surge gate. Site conditions were considered inappropriate or unsafe for sampling in the upper chute reach and downstream of the spill gate. As a result back pack electrofish sampling in the bypassed reach occurred within the two middle reaches. Sampling locations were randomly selected on a seasonal basis. The spatial distribution of habitat classifications and 50-m segments within the 0.75 mile bypassed reach is provided in Appendix C.

Table 5-14 provides a listing of the habitat units downstream of the Pawtucket Dam and within the Lowell bypassed reach that were randomly selected for sampling during the spring, summer, and fall periods of 2019. A total of three, 50-m segments were selected per season.

5.2.2 Sampling Effort

Fish community data were collected from a total of 12, 50-m sample units during the spring, summer, and fall of 2019 (12 sites per season). Effort expended at a sample unit during each of the three seasons consisted of an approximately 50-m back pack electrofish sample. Fish community sampling in the Lowell bypassed reach occurred on June 28 (spring), August 27 (summer) and October 21 (fall). Table 5-15 provides a summary of the back pack electrofish sampling in the Lowell bypassed reach. Bypassed reach sample units selected by season are presented visually in Appendix C.

5.2.3 Species Richness and Composition

A total of 526 individuals representing fourteen fish species were collected during back pack electrofishing efforts within the Lowell bypassed reach during 2019 when all sampling seasons and sample units are considered (Table 5-16). Table 5-17 provides a summary of the bypassed reach community composition by season. Fallfish (39.9%), smallmouth bass (20.3%) and spottail shiner (16.7%) were the three most numerically abundant species within the Lowell bypassed reach during the 2019 sampling. When examined by species, spottail shiner were most abundant during the spring (48.8%), fallfish during the summer (55.0%) and fallfish during the fall (39.9%).

Total catch and community composition from sampling units within the pooled and ledge channel sections of the bypassed reach downstream of Pawtucket Dam are presented in Table 5-18. Fallfish were the most abundant fish species collected within the pooled habitat within the Lowell bypassed reach and downstream of Pawtucket Dam, representing 47% of the total catch. Fish catch from the ledge channel habitat located in the lower portion of the bypassed

reach was dominated by smallmouth bass which represented 60.6% of the total catch from that area. American eel represented 13.8% of the total electrofish catch from the ledge channel habitat within the Lowell bypassed reach.

5.2.4 Relative Abundance

CPUE values for back pack electrofish sampling within the Lowell bypassed reach downstream of Pawtucket Dam were standardized to a fixed unit of time or distance using the equations and methods provided in Section 5.1.4. Catch rates were highest for smallmouth bass, fallfish, and spottail shiner captured by back pack electrofish sampling in the 0.75 mile bypassed reach downstream of Pawtucket Dam during the 2019 sampling (Table 5-19). Values for fish per unit of effort were highest for spottail shiner and fallfish during the spring sampling event, fallfish and smallmouth bass during the summer sampling event and smallmouth bass and redbreast sunfish during the fall sampling event. A listing of CPUE rates for all species by season and habitat type is provided in Appendix D.

5.2.5 Biocharacteristics

Length frequency distributions for fish species where 25 or more individuals were collected and measured during the bypassed reach sampling are presented in Appendix E. The observed range for fish sizes recorded for species observed in the back pack electrofish catch from the reach downstream of the Pawtucket Dam fall within the expected bounds for those species in the northeastern U.S. (Table 5-11). A full listing of catch data is provided in Appendix F.

5.2.6 Habitat and Water Quality Characteristics

Tables 5-21 and 5-22 provide summaries of habitat and water quality information recorded for each of the 9, 50-m sample units surveyed within the Lowell bypassed reach during the spring, summer and fall seasons. A range of substrate types was sampled during each of the three seasons, ranging from areas of boulders to sand-silt-clay habitat. Sampled areas within the Lowell bypassed reach downstream of Pawtucket Dam were characterized by the presence of SAV over 0-25% of the sample area and the presence of general cover over 0-25% of the sample area. Mean water depth (as measured at quarter points of the electrofished area at the upper, middle, and lower points of each transect) was consistent among sample areas and season, ranging from 1.5-2.4 feet.

Water temperature was relatively consistent among sample units within each season[1] and averaged 22.9°C during the spring sampling, 23.8°C during the summer sampling, and 13.1°C during the fall sampling. Dissolved oxygen was measured at 8.9 mg/L or greater at all bypassed reach stations downstream of Pawtucket Dam regardless of season. Conductivity averaged 148 µs/cm during the spring sampling, 194 µs/cm during the summer sampling, and 100 µs/cm during the fall sampling. The average river pH in the bypassed reach was higher during the summer sampling event (7.8) than was observed during the spring (6.5) or fall (6.6).

[1] Water quality readings were available at only sample unit LBYP-011 during the spring event due to a malfunction with the meter handset during sampling.

Table 5–21. Physical habitat measurements recorded for sample units within the bypassed reach downstream of Pawtucket Dam during spring, summer, and fall, 2019

Season	Habitat Type	Sample Unit	Habitat Parameter			
			Dominant Substrate	Pct. SAV	Pct. Cover	Mean Depth (ft)
Spring	Ledge Channels	LBYP-011	Boulder/Rip-Rap	0-25%	0-25%	1.5
	Pooled Section	LBYP-013	Cobble-Gravel	0-25%	0-25%	1.8
	Pooled Section	LBYP-017	Sand-Silt-Clay	0-25%	0-25%	1.7
Summer	Ledge Channels	LBYP-011	Boulder/Rip-Rap	0-25%	0-25%	1.5
	Pooled Section	LBYP-014	Cobble-Gravel	0-25%	0-25%	1.8
	Pooled Section	LBYP-018	Sand-Silt-Clay	0-25%	0-25%	2.4
Fall	Ledge Channels	LBYP-011	Boulder/Rip-Rap	0-25%	0-25%	1.5
	Pooled Section	LBYP-013	Cobble-Gravel	0-25%	0-25%	1.8
	Pooled Section	LBYP-016	Sand-Silt-Clay	0-25%	0-25%	1.6

Table 5–22. Water quality parameters recorded within the bypassed reach downstream of Pawtucket Dam during spring, summer, and fall, 2019

Season	Habitat Type	Sample Unit	Water Quality Parameter			
			Temperature (°C)	Dissolved Oxygen (mg/L)	Conductivity (µs/cm)	pH
Spring	Ledge Channels	LBYP-011	22.9	9.5	148	6.5
	Pooled Section	LBYP-013	*	*	*	*
	Pooled Section	LBYP-017	*	*	*	*
Summer	Ledge Channels	LBYP-011	23.4	9.6	191	7.4
	Pooled Section	LBYP-014	23.9	9.1	195	7.8
	Pooled Section	LBYP-018	24.1	9.4	197	8.1
Fall	Ledge Channels	LBYP-011	13.2	9.8	104	6.3
	Pooled Section	LBYP-013	13.1	8.9	102	6.6
	Pooled Section	LBYP-016	13.0	10.6	95	6.8

* Water quality readings were available at only sample unit LBYP-011 during the spring event due to a malfunction with the meter handset during sampling

5.3 Historic Data

As described in the Lowell relicensing Pre-Application Document (PAD), the Merrimack River is home to a diverse assemblage of fishes, including cold water and warm water species. Stolte (1982; as cited in the Technical Committee for Anadromous Fishery Management of the Merrimack River Basin [Technical Committee] 1997) noted that during the last 150 years, over 15 non-indigenous species such as largemouth bass, smallmouth bass, walleye, common carp, rainbow trout, brown trout, various catfish species and goldfish have established through human introductions within the Merrimack River. At that time, the Merrimack River was identified as home to approximately 50 species of fish, nine of which were anadromous. The slower moving, ponded reaches of the Merrimack contain a higher predominance of warm water species whereas those areas with higher gradient contain the majority of cold water species. Hartel et al. (2002) identified a total of 57 reproducing fish species within the drainage; 21 primary species (i.e., those living full life cycle in freshwater), 8 secondary species (i.e., those with physiological capacity to move between fresh and salt water), 18 introduced species, and 10 diadromous species.

Fish assemblage sampling within the Lowell impoundment and bypassed reach during the spring, summer and fall of 2019 resulted in the identification of 24 fish species (Table 5-23). Of those species, 21 are considered freshwater and 3 are considered as diadromous. Based on information presented in Hartel et al. (2002) species observed during the 2019 fish sampling considered to be native to the Merrimack River watershed in Massachusetts represented 53% of the total catch across all seasons (12 species, 1,249 individuals). Conversely, species classified by Hartel et al. (2002) as introduced to the Merrimack River watershed represented 47% of the total catch across all seasons (12 species, 1,119 individuals).

Table 5–23. Classifications for fish species recorded within the Lowell impoundment and bypassed reach downstream of Pawtucket Dam during spring, summer, and fall, 2019

Common Name	Freshwater Resident	Diadromous	Native	Introduced
Alewife		X	X

Yellow Perch	X		X	

6 Summary

The Lowell RSP identified two specific objectives for the fish assemblage study including (1) sampling to describe the fish assemblage structure, distribution, and abundance within the Project affected area along spatial and temporal gradients, and (2) a comparison of historical records of species occurrence with observations from this study.

Fish community sampling was conducted over spatial (impoundment versus bypassed reach) and temporal (spring, summer, and fall) gradients during 2019. Within the Lowell impoundment, fish were collected from standardized 500-m transects using a stratified random sampling design where mesohabitat type (i.e., impoundment, run, pool) was used to stratify. Once sites were identified, impoundment sampling was conducted via nighttime boat electrofishing, experimental gill netting, and minnow traps. Fish community data were collected from a total of 36, 500-m sample units during the spring, summer, and fall of 2019 (12 sites per season). A total of 1,847 individuals representing twenty-two fish species were collected from the Lowell impoundment during 2019 when all sampling seasons and sample units are considered. Spottail shiner (23.0%), redbreast sunfish (20.5%) and smallmouth bass (12.3%) were the three most numerically abundant species within the Lowell impoundment during the 2019 sampling. Centrarchid species were the most abundant within impoundment habitat with redbreast sunfish (24.2%), pumpkinseed (14.2%), and smallmouth bass (12.5%) representing the three most abundantly sampled species. Spottail shiner were the most abundantly sampled fish species in the pool (28.4%) and run (46.3%) habitat areas. The majority of catch in the impoundment was observed during boat electrofishing efforts.

Within the Lowell bypassed reach, fish were collected from standardized 50-m transects using a stratified random sampling design where habitat type was used to stratify. Site conditions were considered inappropriate or unsafe for sampling in two portions of the bypassed reach (i.e., the upper chute reach and downstream of the spill gate) and as a result back pack electrofish sampling in the bypassed reach occurred within the two middle reaches (i.e., the pooled section immediately downstream of the School Street Bridge and ledge channel area in the vicinity of the University Ave Bridge). A total of 526 individuals representing fourteen fish species were collected during back pack electrofishing efforts within the Lowell bypassed reach during 2019 when all sampling seasons and sample units are considered. Fallfish (39.9%), smallmouth bass (20.3%) and spottail shiner (16.7%) were the three most numerically abundant species within the Lowell bypassed reach during the 2019 sampling. Fallfish were the most abundant fish species collected within the pooled habitat within the Lowell bypassed reach and downstream of Pawtucket Dam, representing 47% of the total catch. Fish catch from the ledge channel habitat located in the lower portion of the bypassed reach was dominated by smallmouth bass which represented 60.6% of the total catch from that area.

Fish assemblage sampling within the Lowell impoundment and bypassed reach during the spring, summer and fall of 2019 resulted in the identification of 24 fish species. Approximately 53% of individuals collected during the 2019 sampling were classified as fish species native to the Merrimack River watershed in Massachusetts (12 species, 1,249 individuals). Conversely,

47% of the total catch across all seasons were classified as introduced to the Merrimack River watershed (12 species, 1,119 individuals).

7 Variances from FERC-Approved Study Plan

There was no variance from the methodologies and schedule as described in the FERC-approved study plan.

1 Introduction

A radio-telemetry assessment of the effects of project operation on downstream migrating juvenile alosines was conducted in support of the relicensing for the Lowell Hydroelectric Project (Lowell or Project), Federal Energy Regulatory Commission (FERC) No. 2790, as identified in the Revised Study Plan (RSP) submitted by Boott Hydropower, LLC (Boott) on January 28, 2019. The approach and methodology described in the RSP for the juvenile alosine study was approved without modifications by FERC in its Study Plan Determination (SPD) letter dated March 13, 2019.

In accordance with 18 C.F.R. § 5.15(c), Boott filed their Initial Study Report (ISR) with FERC on February 25, 2020. As described in the ISR, data analyses were in progress and scheduled for completion during 2020. On June 12, 2020 FERC issued a Revised Process Plan and Schedule and Determination on Requests for Study Modifications for the Lowell Hydroelectric Project (Revised PPS). In accordance with the Revised PPS, Boott filed their Revised ISR with FERC on September 30, 2020, which contained a full report for the Juvenile Alosine Downstream Passage Assessment. Boott held a revised ISR meeting on October 15, 2020 and representatives from FERC, U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), Massachusetts Division of Fisheries and Wildlife (MADFW), Massachusetts Division of Marine Fisheries (MDMF), and the New Hampshire Fish and Game Department (NHFGD) had the opportunity to provide comments. Subsequent to the September 30, 2020 ISR meeting, the MADFW (November 25, 2020), NMFS (November 30, 2020), and MDMF (November 30, 2020) submitted written comments on the ISR to FERC. A summary of comments received and the corresponding responses is provided in Appendix D of this report. Where noted, the body of the report has been updated to reflect the content of those comments.

This final technical report provides a description of the objectives, methodologies and results of the 2019 radio-telemetry assessment to evaluate the effect of operations on downstream migrating juvenile alosines at the Lowell Project.

2 Objectives

The goal of this study was to determine the Lowell Project's impact on the outmigration of juvenile alosines.

Specific objectives included:

- Assess the effects of the Project on the timing, orientation, passage routes, and migration rates of juvenile alosines.
- Determine the proportion of juvenile alosines that select the Pawtucket Canal versus the E.L. Field Powerhouse, downstream bypass facility, or dam spill as a downstream passage route, under varied operational conditions.

- Determine if there are any delays associated with downstream movement related to either dam spill or the E.L. Field Powerhouse due to operations.

3 Project Description and Study Area

The Lowell Project is located at River Mile (RM) 41 on the Merrimack River in the City of Lowell in Middlesex County, Massachusetts, with an impoundment extending approximately 23 miles upstream into Hillsborough County, New Hampshire. The existing Lowell Project consists of: (1) a 1,093-foot-long, 15-foot-high masonry gravity dam (Pawtucket dam) that includes a 982.5-foot-long spillway with a crest elevation of 87.2 feet National Geodetic Vertical Datum 1929 (NGVD 29) topped by 5-foot-high pneumatically-operated crest gates deployed in five independently-operable zones; (2) a 720-acre impoundment with a normal maximum water surface elevation of 92.2 feet NGVD 29; (3) a 5.5-mile-long canal system which includes several small dams and gatehouses; (4) a powerhouse (E.L. Field) which uses water from the Northern Canal and contains two turbine-generator units with a total installed capacity of 15.0 megawatts (MW); (5) a 440-foot-long tailrace channel; (6) four powerhouses (Assets, Bridge Street, Hamilton, and John Street) housed in nineteenth century mill buildings along the Northern and Pawtucket Canal System containing 15 turbine-generator units with a total installed capacity of approximately 5.1 MW; (7) a 4.5-mile long, 13.8-kilovolt transmission line connecting the powerhouses to the regional distribution grid; (8) upstream and downstream fish passage facilities including a fish elevator and downstream fish bypass at the E.L. Field powerhouse, and a vertical-slot fish ladder at the Pawtucket dam; and (9) appurtenant facilities. At the normal pond elevation of 92.2 feet NGVD 1929 (crest of the pneumatic flashboards), the surface area of the impoundment encompasses an area of approximately 720 acres. The gross storage capacity between the normal surface elevation of 92.2 feet and the minimum pond level of 87.2 feet is approximately 3,600 acre-feet. The Project operates essentially in a run-of-river (ROR) mode using automatic pond level control, and has no usable storage capacity.

The study area for the juvenile alosine passage assessment included the section of the Merrimack River from the point approximately 1.0 mile upstream of the Pawtucket Gatehouse to a point approximately 2.1 miles downstream from the E.L. Field Powerhouse tailrace (Figure 3-1). The Upper Pawtucket Canal and Guard Locks facility were also considered as part of the study area.

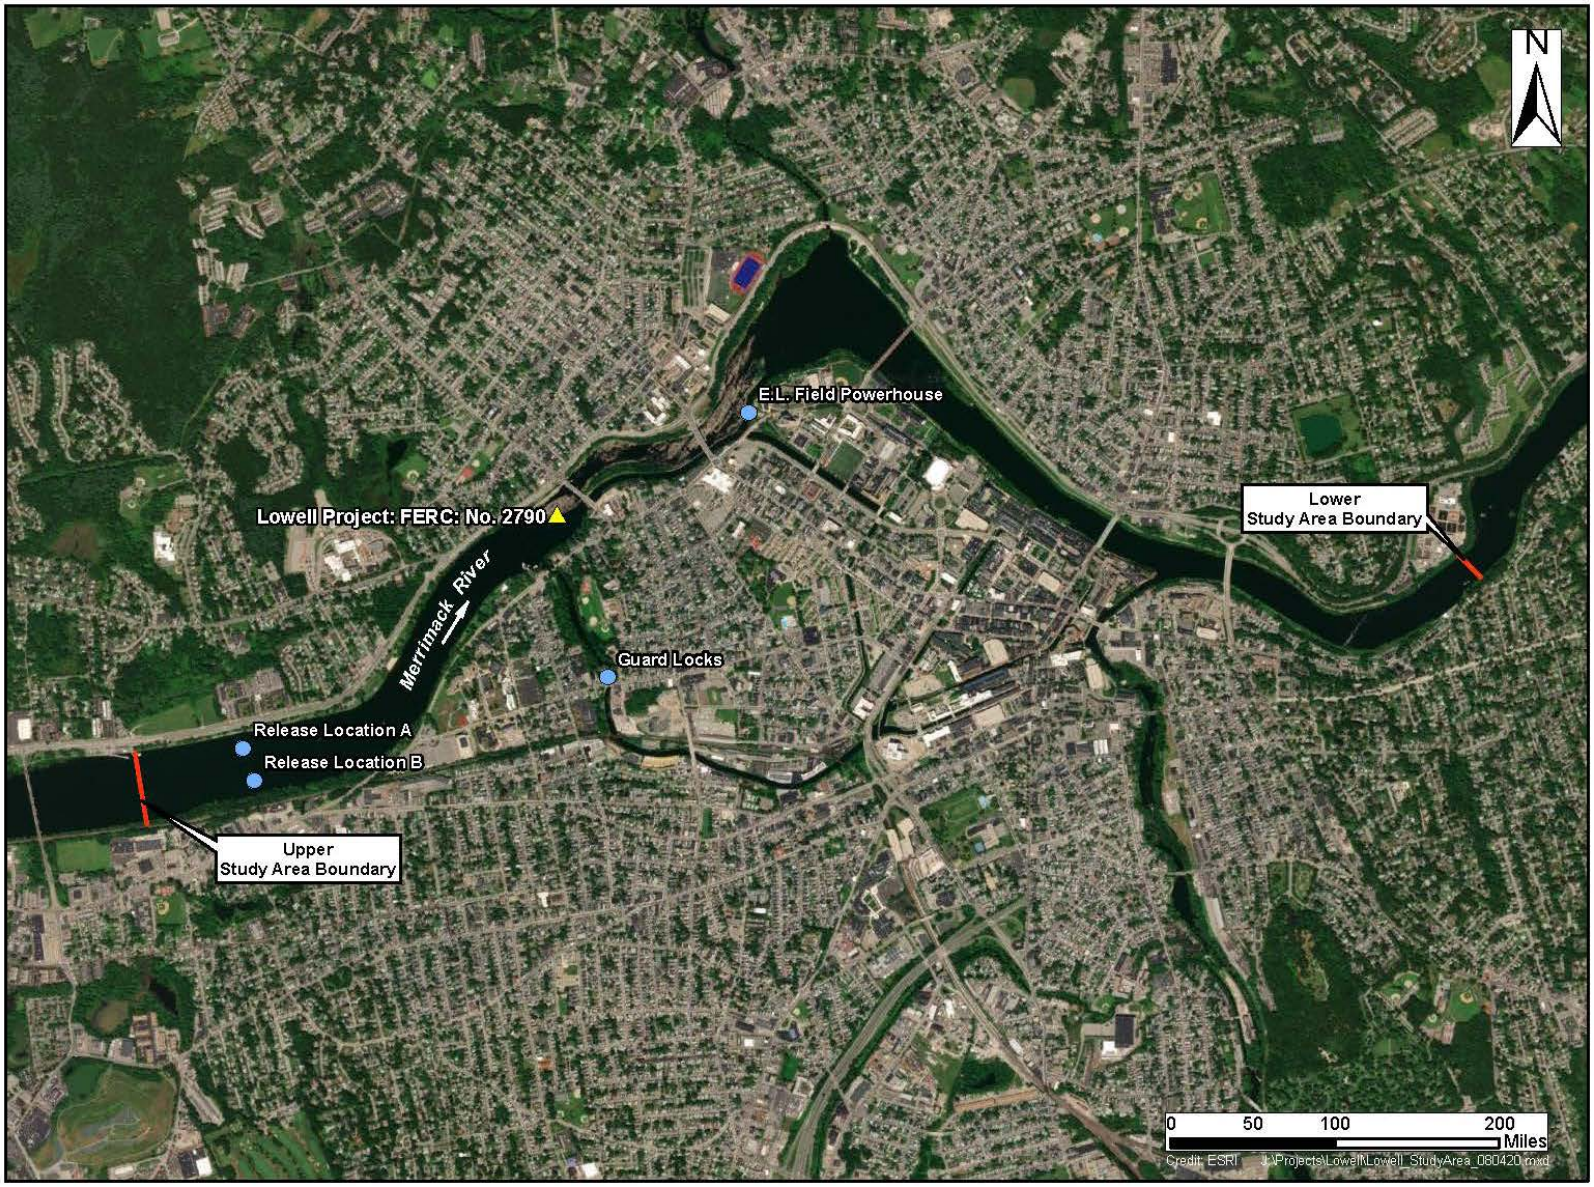

Figure 3–1. Merrimack River study reach considered during the fall 2019 juvenile alosine downstream passage assessment.

4 Methods

Downstream passage of juvenile alosines through the Lowell Project reach was evaluated using radio-telemetry during the fall of 2019. Following the release of radio-tagged individuals into the Lowell impoundment at a point approximately 1.0 miles upstream of the Pawtucket Gatehouse, downstream movements were monitored using a series of stationary radio-telemetry receivers in place at the Project as well as stationary monitoring stations installed at bank-side locations upstream and downstream of the Project to inform on general movements, distribution among available passage routes and continued downstream travel.

4.1 Radio Telemetry Equipment

Movements of radio-tagged individuals during the 2019 study were recorded via a series of stationary radio-telemetry receivers. Radio-telemetry equipment used during the evaluation of downstream passage at Lowell included Orion receivers, manufactured by Sigma Eight, as well as SRX receivers manufactured by Lotek Wireless. Each receiver was paired with either an aerial or underwater antenna (dropper antenna). Aerial antennas (four or six element Yagi) were utilized to detect radio-tagged individuals within the larger, more open sections of river, such as within the tailrace or at locations downriver of Lowell. Dropper antennas were fixed at downstream passage locations (e.g., downstream bypass).

Juvenile alosines radio-tagged during 2019 were equipped with a Lotek NTF-1-1 transmitter. The NTF-1-1 transmitters measured approximately 5 x 3 x 9.6 mm, weighed 0.24 grams and had an estimated battery life of 13 days when set at a 2.0 second burst rate. Each transmitter was coded to emit a unique identifying signal so that individual juvenile alosines could be identified by any given receiver.

4.2 Monitoring Stations

The RSP identified a total of ten monitoring stations to be set up at Lowell for the downstream juvenile alosine passage assessment. Each of the ten monitoring locations identified in the RSP were installed as described and each location consisted of a data-logging receiver, antenna, power source, and were configured to receive transmitter signals from a designated area continuously throughout the study period. During installation of each station, range testing was conducted to configure the antennas and receivers in a manner which maximized detection efficiencies at each location. The operation of the radio telemetry receivers was initially established during installation, then confirmed throughout the study period by using beacon tags. A number of beacon tags were stationed at strategic locations within the detection range of either multiple or single antennas, and they emitted signals at programmed time intervals. These signals were detected and logged by the receivers and used to record the functionality of the system throughout the study period.

The locations of monitoring stations installed for the 2019 juvenile alosine passage evaluation at Lowell are outlined here and presented in Figures 4-1 through 4-3.

Monitoring Station 20: This station was installed at a location downstream of the release location and upstream of Pawtucket Dam and was intended to detect radio-tagged juvenile alosines following their initial downstream movement away from the release location. Station 20 consisted of a single Lotek SRX receiver and an aerial antenna oriented perpendicular to the river channel and was located at a point approximately 0.6 miles upstream of the Pawtucket Gatehouse.

Monitoring Station 21: This station consisted of a single Lotek SRX radio-receiver and an aerial antenna located at the Project compressor building. Station 21 was installed and calibrated to provide information on radio-tagged juvenile alosines as they approached the upstream face of Pawtucket Dam. Detections at this location were used to inform on the arrival of radio-tagged juveniles at the Project.

Monitoring Station 24: Monitoring Station 24 consisted of a Lotek SRX radio-receiver and an aerial antenna installed to detect radio-tagged juvenile alosines which had entered the Pawtucket Canal system. The entrance to the Pawtucket Canal sits at a point upstream of the Pawtucket Dam and the Northern Canal. Station 24 was located at the Guard Locks, approximately 1,700 feet downstream from the entrance to the canal. The monitoring zone for Station 24 was focused downstream of the Guard Locks facility to ensure any detections recorded at that location were of fish which had definitively entered the downtown canal system.

Monitoring Station 26: Station 26 consisted of a single Orion radio-receiver and aerial antenna installed and calibrated to provide coverage of the upstream side of the Pawtucket Gatehouse. This station informed on radio-tagged juvenile alosines which had approached the upstream side of the Pawtucket Gatehouse.

Monitoring Station 28: Station 28 consisted of a single Lotek radio-receiver and aerial antenna installed and calibrated to provide coverage of the downstream side of the Pawtucket Gatehouse. This station informed on radio-tagged juvenile alosines which had successfully passed through the Pawtucket Gatehouse and entered the Northern Canal.

Monitoring Station 30: Station 30 consisted of a single Lotek SRX radio-receiver and aerial antenna installed and calibrated to provide detection information for radio-tagged juvenile alosines that passed through the Pawtucket Gatehouse, entered the E.L. Field Powerhouse forebay (i.e., the downstream potion of the Northern Canal) and were in the vicinity of the entrance to the downstream bypass and intake racks.

Monitoring Station 32: This station consisted of a single Orion radio-receiver and underwater drop antenna installed and calibrated to provide detection information for radio-tagged juvenile alosines exiting the forebay via the downstream bypass.

Monitoring Station 34: Station 34 consisted of a single Lotek SRX radio-receiver and aerial antenna installed and calibrated to scan across the bypassed reach at a point downstream of where the surge gate enters from the power canal and upstream from the downstream bypass.

Detections at this location confirmed downstream passage of juvenile alosines using the spillway or surge gate.

Monitoring Station 36: This station consisted of a single Lotek radio-receiver and aerial antenna installed at a location overlooking the project tailrace. Detections at this location were used to confirm the downstream passage of radio-tagged juvenile alosines via the E.L. Field powerhouse turbine units.

Monitoring Station 38: This station was installed at a point along the mainstem of the Merrimack River downstream of both the E.L. Field Powerhouse tailrace and the confluence with the Concord River. Station 38 consisted of a single Lotek SRX receiver and aerial antenna oriented perpendicular to the river channel and was installed at the Lowell Waste Water Treatment Plant, approximately 2.1 miles downstream of the tailrace.

4.3 Tagging and Release Procedures

Juvenile alosines were collected by boat electrofishing from Turtletown Pond in Concord, NH. Following collection, juvenile alosines were transported by tank truck to a temporary holding facility at the Garvins Falls Dam on the Merrimack River, Bow, NH. Once transferred to the holding tanks, collected juvenile alosines were allowed to acclimate for a minimum of 24 hours prior to tagging in order to observe for any latent post capture mortality.

NTF-1-1 transmitters were attached to a dry fly hook using bonding cement. The hook was inserted posterior to the dorsal fin with the majority of the tag and antenna trailing behind the insertion point (Figure 4-4). After tagging, fish were held in holding containers and maintained in ambient Merrimack River water until they were transported to the release site. As part of the 2019 passage route evaluation, a total of 10 separate release groups, each comprising up to 15 tagged and 15 untagged juvenile alosines, were released. Each release group was separated into two holding containers, each consisting of 7-8 tagged and 7-8 untagged juvenile alosines resulting in a total of 15 fish per container. Tagged juvenile alosines driven to the Rourke Brothers Boat Ramp in Lowell, MA and were then transported by boat to a location approximately 1.0 miles upstream of the Pawtucket Gatehouse. During each release event, the two holding containers were lowered over the side of the boat and the tagged and untagged juvenile alosines were allowed to volitionally exit the container. On each release date the total number of individuals placed in the river were split over two separate release points, one in the eastern third of the river and the other in the western third of the river. The date, time, and release location of each group of tagged alosines was recorded.

4.4 Data Collection

4.4.1 Stationary Telemetry Data

Receiver downloads occurred three to four times weekly during the period from the initial tag and release event until November 12, 2019 (i.e., six days beyond the anticipated battery life for radio-transmitters used for the final test fish release group (October 24, 2019)). Backup copies of all telemetry data were made prior to receiver initialization. Field tests at the time of

download to ensure data integrity and receiver performance included confirmation of file integrity, confirmation that the last record was consistent with the downloaded data (beacon tags were critical to this step), and lastly, confirmation that the receiver was operational upon restart and actively collecting data post download. Within a data file, transmitter detections were stored as a single event (i.e., single data line). Each event included the date and time of detection, frequency, ID code, and signal strength.

4.4.2 Manual Telemetry Data

To provide supplemental detection information to the stationary receiver data set, manual tracking was conducted on a number of occasions from the time of initial release through mid-November, 2019. Manual effort was exerted in the vicinity of the Lowell Project (i.e., tailrace and headpond immediately upstream of Pawtucket Dam) on most dates when stationary telemetry equipment was checked. In addition, a number of boat or truck-based efforts were conducted to look for radio-tagged individuals within the lower Lowell impoundment and the reach of the Merrimack downstream to Lawrence.

4.4.3 Operational and Environmental Data

Merrimack River water temperature was recorded via a continuously operating logger installed within the Lowell intake canal. Hourly records for operations data were provided by Boott for the 2019 evaluation period and included:

- Headpond elevation (ft);
- Power canal elevation (ft);
- Headpond-power canal differential (ft);
- Tailrace elevation (ft);
- Head differential for E.L. Field turbines (ft);
- Total inflow (cfs);
- Unit 1 discharge (cfs) and output (KW);
- Unit 2 discharge (cfs) and output (KW);
- Downstream bypass discharge (cfs);
- Upstream fishway discharge (cfs);
- Downtown canal flow (cfs); and
- Spill flow through the bypassed reach (cfs).

4.5 Data Analysis

The tagging, telemetry and Project operations data sets collected as part of this effort were examined and used to evaluate a number of metrics related to downstream passage success and movement through the Project area.

4.5.1 Downstream Movement and Passage Route Selection

A complete record of all valid stationary receiver detections for each radio-tagged juvenile alosines was generated. The pattern and timing of detections in these individual records were reviewed, and a route of passage as well as project arrival and passage times were assigned to

each radio-tagged individual. In the instance that a downstream route could not be clearly determined from the collected data, the passage event for that particular fish was classified as 'unknown'.

Where data were available, project residence times were calculated. Upstream residence duration was defined as the duration of time from the initial detection at Station 21 until the determined time of downstream passage. Time spent immediately upstream of the dam was further evaluated using initial detection times for radio-tagged juvenile alosines at Monitoring Stations 26 and 28 to provide an understanding of passage times associated with moving through the Pawtucket Gatehouse and entering into the Northern Canal approach to the E.L. Field powerhouse (i.e. "Pawtucket Gatehouse Passage"). Power canal residency was evaluated using the initial detection at Station 28 and the time of downstream passage to provide an understanding of the time spent within the Northern Canal prior to passage route selection (i.e. "Northern Canal Residence").

4.5.2 Time to Event Analysis

4.5.2.1 Cox Proportional Hazard Model

Utilizing available methodology for quantifying fish passage performance (Castro-Santos and Perry 2012), multi-variate Cox proportional hazard models were developed to assess the impact of various operational and environmental variables on the rate of passage success. Operational and environmental variables considered as part of this analysis included:

- Merrimack River water temperature (°C);
- Head differential (ft) at the Pawtucket Gatehouse (i.e., headpond vs. Northern Canal);
- Bypassed reach spill flow (cfs);
- E.L. Field turbine discharge (cfs);
- Merrimack River inflow (cfs); and
- E.L. Field head differential (ft) (i.e., Northern Canal vs. tailwater).

Although additional variables such as turbine operation at E.L. Field (i.e., Unit 1, Unit 2, both, or neither) and head pond elevation (ft) were available, there was not enough resolution in the data during the fall 2019 passage period to provide meaningful results. This assessment on the rate of passage success focused on approach events at (1) the Pawtucket Gatehouse (i.e., Station 25), and (2) at the E.L. Field Powerhouse (i.e., Station 29).

Regression models for the time to event analyses were constructed using the *coxph*() function from the package "*survival*" in R (R Core Team 2020) and were used to evaluate the rate of passage success and identify operational hazards at sites which contained a physical barrier or a structure through which tagged individuals would have to navigate (i.e., the Pawtucket Gatehouse and E.L. Field Powerhouse).

The Cox proportional hazard regression can be described as a hazard function to evaluate the proportionate risk at time (t) such that

$$h(t) = h_0(t) \times exp(b_1x_1 + b_2x_2 + \ldots + b_ix_i)$$

where $h(t)$ represents that hazard at a given time point which is equal to the initial or baseline hazard at time 0:00 ($h_0(t)$) multiplied by e (the base of the natural logarithm) to the power of the additive relationship between each covariate (x_i) multiplied by its associated coefficient (b_i).

From the above equation, the relative impact of an operational parameter on the rate of passage success is represented by its associated coefficient. The hazard ratio of a given operational parameter is calculated by exponentiating the coefficient of a given parameter, which represents that multiplicative impact of that parameter. It is important to note that exponentiating these coefficients makes the value relative to a value of 1 (e^0), which represents a baseline of no hazard. For example, if the hazard ratio is greater than 1, e.g., 1.5, that will be interpreted as that covariate increasing the risk of passage failure by a factor of 1.5. Alternatively stated, a hazard ratio of 1.5 indicates that the associated covariate increases the risk by 50% as it is 0.5 greater than 1. In contrast, a hazard ratio below 1, e.g., 0.75, indicates that the associated covariate reduces the risk of passage failure by a factor of 0.75, or 25%. In short, a hazard ratio >1 indicates an increase in the risk of passage failure, a hazard ratio of 1 indicates no significant directional effect on passage, and a hazard ratio <1 indicates a reduction in the risk of passage failure.

4.5.2.2 Model Evaluation and Selection

As is the case with any statistical model, the type of model selected makes inherent assumptions about the nature of the data being modelled. The primary assumption of a Cox proportional hazard model is that the hazards are proportional. However, this assumption is not always appropriate for the data. As a result, the *cox.zph()* function was used during this assessment to assess the validity of the proportional hazard assumption. This function assessed scaled Schoenfield residuals to evaluate whether Cox regression residuals of each covariate in addition to the model as a whole are independent of time. In the event that the Schoenfield residuals are not independent of time, it can be said that the assumption of proportional hazards is violated and a Cox proportional hazards model may be misrepresentative of the true relationships between the selected covariates and passage success.

4.5.2.3 Event Definition

To evaluate the impact of operational parameters on passage success, instances of passage success and failure required definition and represent the 'events' (or passage attempts) in this analysis. Ostensibly, the transmitters deployed during this study should transmit a signal that when within range of a particular receiver will be detected every 2.0 seconds. However, various sources of outside noise or areas of poor coverage due to structures, etc. introduce variation into the frequency of detection for a unique transmitter's signal. Given that different site locations and receiver types are subject to varying degrees of ambient noise, the duration between successive detections was calculated for each tagged individual at each receiver location. A threshold interval for determining continued presence of a transmitter within the detection zone of a specific receiver was identified as the 95th percentile of the observed set of interval durations. This value was calculated at 14.5 minutes for Station 26 and 25.2 seconds

for Station 30. These two threshold values were then used to delineate when each event was started and completed for a tagged individual. The lengthier threshold value at Station 26 was likely a function of multiple entrances and exits of radio-tagged juveniles from the relatively limited detection zone (receiver was adjusted to only provide coverage in area immediately upstream of the Pawtucket Gatehouse). The departure of a radio-tagged individual from the detection zone of a particular receiver was determined when the time interval between successive detections exceeded the specific threshold interval for that zone.

From this, a passage failure event (assigned a value of 0) was defined as any duration where all detections lay within the 95^{th} percentile of durations for all individuals at that site. Passage failure represents events in which a tagged individual enters the field of detection at a given site without passing to the next site (i.e., moving downstream) in the system. A passage success event (assigned a status of 1) was defined using the final instance of detection for a tagged individual at a singular site where that tagged individual was next detected at a downstream receiver (i.e., successfully passed). Passage success/failure (1/0) was used as the status coinciding with time in the Cox proportional hazard models. After defining passage events for every individual, the time duration for the regression was defined as the duration from one event to the next.

5 Results

5.1 Merrimack River Conditions and Lowell Project Operations

Figure 5-1 presents the Merrimack River flow and water temperature for the period of time from the first alosine release on October 9 until the end of the monitoring period on November 12, 2019. Merrimack River water temperature at the Project ranged from 16°C to 6°C during the monitoring period. Total river flow values represent the reported inflow at the Lowell Project and ranged between 1,089 and 11,435 cfs during the fall monitoring period. Figure 5-2 presents the monthly flow duration curves prepared for Lowell during the development of the Preliminary Application Document. The median flow condition at the Project is approximately 3,600 cfs during October and 6,500 cfs during November. Merrimack River conditions have a ~20% probability during October and a ~38% probability during November to exceed the ~8,000 cfs capacity of the E.L. Field powerhouse.

Table 5-1 summarizes the percentage of inflow records from the 2019 study period categorized by volume (to the nearest 1,000 cfs) as well as the percentage of time that each volume category is historically exceeded[1]. To help characterize the 2019 passage season, monthly exceedance probabilities less than 0.35 were classified as "high" flow conditions, 0.35 to 0.65 were classified as "normal" flow conditions, and greater than 0.65 were classified as "low" flow conditions. Inflows at the Project for the period October 9 through 31 were representative of high flow conditions (i.e., those with a probability of exceedance of less than 0.35) for 35% of the period, normal flow conditions (i.e., those with a probability of exceedance of 0.35-0.65) for 29% of the time and low flow conditions (i.e., those with a probability of exceedance of greater than 0.65) for 36% of the time. For the month of November, inflows were representative of high flow conditions 19% of the time, normal flow conditions 30% of the time and low flow conditions 51% of the time.

Flow duration information for the months of October and November (combined) is presented in Figure 5-3. The median flow condition during the two month period is near 5,000 cfs. When characterized using the flow condition criteria above, inflows at the Project for the period October 9 through November 12 were representative of high flow conditions (i.e., those with a probability of exceedance of less than 0.35) for 14% of the period, normal flow conditions (i.e., those with a probability of exceedance of 0.35-0.65) for 59% of the time and low flow conditions (i.e., those with a probability of exceedance of greater than 0.65) for 27% of the time (Table 5-1).

Figure 5-4 summarizes the allocation of water among the E.L. Field powerhouse, bypassed reach, downstream fishway, and downtown canal system at Lowell. Turbine units were in operation at the E.L. Field powerhouse for the duration of the study period with Unit 1 in operation throughout the study and Unit 2 coming online at 0900 on October 16. The

[1] Estimates of monthly exceedance estimated from monthly flow duration curves provided in Appendix H of the PAD.

downstream bypass was operated throughout the study period, passing approximately 132 cfs (i.e., 2% of the nameplate capacity of the E.L. Field turbine units; 6,600 cfs). A major spill event, associated with increases in river flows, occurred during the monitoring period. The event occurred from approximately October 29 to November 5, towards the end of the monitoring period. Flows to the downstream canal system represented between 15-20% of the 2,000 cfs canal capacity during October and 20% of the 2,000 cfs canal capacity for the majority of monitoring during early November. Due to overriding safety concerns, Boott limited operation of the turbine units within the downtown canal system during the study period. To the extent possible, Boott's operations staff attempted to operate the canal system as if there were canal units available, by opening gates when river flows exceeded the hydraulic capacity of the E.L. Field turbines (7,000 to 8,000 cfs). As a result, flows through the downtown canal system were largely restricted to passage via open gates. The Licensee manually recorded gate and unit settings once weekly during the study period within the downtown canal system. A breakdown of those values and related discharge estimates are provided in Appendix A.

Table 5–1. Frequency of occurrence of river inflow at Lowell (to nearest 1,000 cfs) during 2019 juvenile alosine downstream passage assessment and corresponding percentage of time flows are historically exceeded.

River Flow (Nearest 1k)	October 9-30, 2019		November 1-12, 2019		Oct 9 - Nov 30, 2019

5.2 Monitoring Station Functionality

Radio-tagged juvenile alosines were released into the Merrimack River beginning in early October, 2019 and the RSP called for continuous monitoring at each stationary receiver location for 14 days after the final release of tagged fish. Figure 5-5 provides an overview of the continuity of monitoring at each of the ten stationary receiver locations during the fall period from the date of first release until November 12, 2019. The majority of the radio-telemetry monitoring stations installed to evaluate passage at Lowell during the fall study operated without issue for the full period.

Interruptions in continuous coverage were observed at two locations during the latter part of the 2019 monitoring period. These locations included Station 28 (downstream side of the Pawtucket Gatehouse) from 1900 on November 9 through the end of the monitoring period at Station 38 (receiver downstream of Lowell) from 0000 on November 5 to 1300 on November 7. There were no radio-tagged juvenile alosines which approached the Pawtucket Gatehouse after October 25 nor any downstream passage events for radio-tagged individuals after October 31. The late-season timing of these relatively short interruptions in coverage likely eliminated any potential impacts to the study results for monitoring juvenile alosine passage.

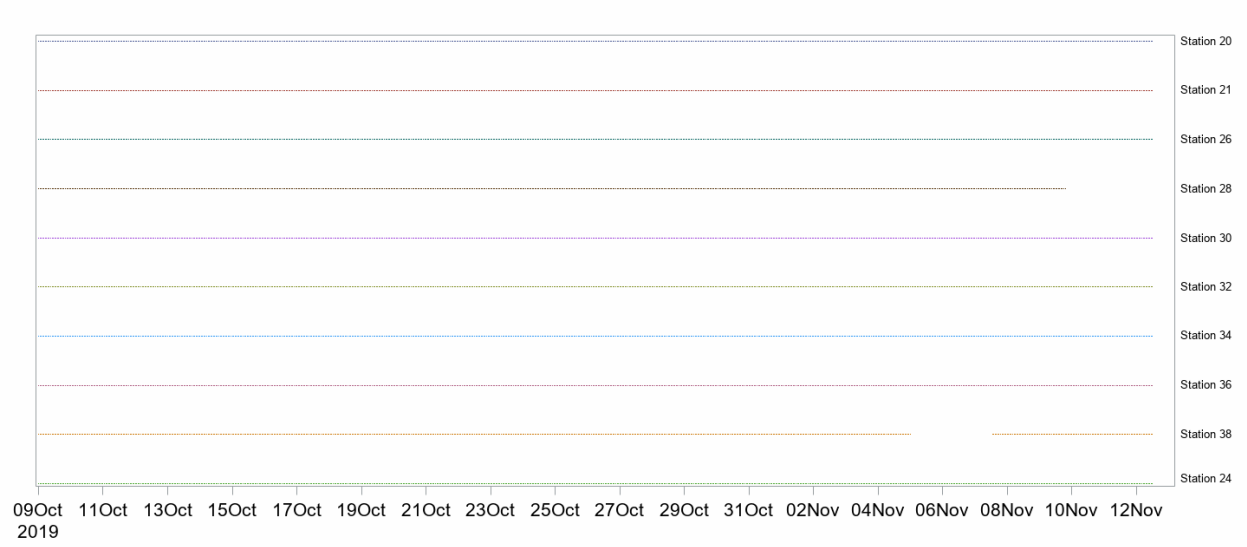

Figure 5–5. Operational coverage for telemetry receivers at Lowell during the juvenile alosine downstream passage assessment, October 9 to November 12, 2019.

5.3 Juvenile Alosine Tagging and Releases

Juvenile alosines were radio-tagged and released approximately 1.0 mile upstream of the Pawtucket Gatehouse starting on October 9 and ending on October 24. Table 5-2 provides a summary of the release dates and number of individuals released during the 2019 passage assessment. A total of 145 radio-tagged juvenile alosines were released over a span of 16 days and were potentially available for evaluation of downstream passage at Lowell. All test fish originated from Turtletown Pond in Concord, NH and were released with an equal number of untagged fish to promote schooling behavior. Fish tagged and released upstream of Lowell as part of the fall downstream passage evaluation ranged in length from 116 to 155 mm TL with a mean length of 134 mm. The majority of test fish (90%) measured between 125-144 mm. Mean length among release groups were similar across all ten release dates. A full listing of individuals radio-tagged and released as a part of this evaluation is included in Appendix B.

5.4 Project Arrival and Upstream Residence Duration

Releases of radio-tagged juvenile alosines were initiated on October 9, 2019. The distribution of arrival dates for radio-tagged alosines at the Pawtucket Dam as indicated by detection at Station 21 is provided in Figure 5-6. Initial detections for tagged alosines were recorded over a range of dates from October 9 through October 25 with all radio-tagged fish which successfully transited the approach reach doing so within a the first or second day after release.

Upstream residence (i.e., the duration of time radio-tagged individuals were present upstream of the Pawtucket Dam as determined for all individuals which approached and eventually passed downstream) was calculated as the duration of time from initial detection at Station 21 until confirmed downstream passage. When all individuals are considered, the upstream residence duration for radio-tagged juvenile alosines ranged between 0.4 hours to 4.8 days (Table 5-3; Figure 5-7). The median duration of time spent immediately upstream of the dam structure was 1.3 days, ranging from 0.8 hours to 3.6 days when examined among the ten separate release dates. Of the radio-tagged juvenile alosines which approached Pawtucket Dam, 42% passed in less than 24 hours and 68% in less than 48 hours after initial detection.

Outmigrating juvenile alosines encountering the Pawtucket Dam can (1) pass through the Pawtucket Gatehouse and enter the power canal (Northern Canal), (2) pass downstream over Pawtucket Dam via spill, or (3) enter the Pawtucket Canal and navigate downstream via the downtown canal system. The majority of radio-tagged juvenile alosines were determined to have passed through the Pawtucket Gatehouse and entered the Northern Canal to approach the E.L. Field powerhouse. The duration of time required to pass through the Pawtucket Gatehouse was evaluated as the difference in time of the initial detection for each individual radio-tagged juvenile at Stations 26 and 28 which independently monitored the upstream and downstream sides of that structure. The median duration of time for radio-tagged juvenile alosines to pass downstream of the Pawtucket Gatehouse following their approach at that structure was 0.1 hours (range <0.1 hours to 0.4 hours; Table 5-4), indicating rapid passage at that structure.

Whereas passage of radio-tagged juvenile alosines through the Pawtucket Gatehouse structure occurred relatively rapidly, the transit time for those tagged individuals to pass downstream of the Project after entering into the Northern Canal ranged from 0.2 hours up to 4.7 days (median = 22.0 hours; Table 5-5). Of those individuals, 56% were resident in the power canal upstream of E.L. Field for 24 hours or less. The overall percentage of radio-tagged juvenile alosines departing the power canal within 48 hours of entry increased to 68%.

5.5 Downstream Passage

A total of 145 radio-tagged juvenile alosines were released upstream of the Pawtucket Dam during the fall of 2019. The final disposition of all tagged juveniles is presented in Table 5-6. Three radio-tagged individuals (2% of total) did not approach the Pawtucket Dam following their initial release (as indicated by no detection at Station 21 or points further downstream). Three radio-tagged juvenile alosines (2.1% of the total approaching the dam) were determined to have entered the downtown canal system as evidenced by detection at the Guard Locks (Station 24). The majority of individual passed downstream of the Project via spill over the Pawtucket Dam (9.2%) or entered the power canal and approached the E.L. Field Powerhouse to pass downstream via the downstream bypass (12.0%) or turbine units (57.7%). A portion of individuals (18 fish; 12.7% of the total approaching the dam) failed to pass downstream. Reasons for this may include transmitter loss, predation, other mortality, or failure to locate a viable passage route. A definitive passage route could not be determined for nine individuals (6.3% of the total approaching the dam) and as a result those fish were classified as unknown.

Radio-tagged alosines were detected passing downstream between the dates of October 12 and October 31 (Figure 5-8) with a primary peak representing individuals associated with a number of release groups occurring on October 17-18. Passage events on the dates of October 17 and 18 represented 37.3% of the passage observed for radio-tagged juveniles during the study. Figure 5-9 presents the distribution of downstream passage events on an hourly basis. Passage occurred at almost all hours of the day with the highest passage rate occurring during the 1600 hour (10.7%). Overall passage was fairly uniform with 52% of detected events occurring between the hours of 1700 and 0500 and 48% between the hours of 0600 to 1600.

For each of the 115 individuals which were confirmed to have passed downstream of Lowell via a known passage route (i.e., turbine, downstream bypass, spill, or downtown canal system) the hourly record of Project operations (Section 5.1) at the time of passage was reviewed. The discharge at the selected route was identified and contrasted with the cumulative discharge for all non-selected routes at the time of downstream passage (Table 5-7). The majority of radio-tagged juvenile alosines passing downstream at Lowell did so via the E.L. Field turbine units (Table 5-6). The median discharge through the two E.L. Field turbine units at the time of passage for those individuals was 3,121 cfs. When examined by passage route, the median percentage of passage route flow at each known downstream passage route represented 79% of inflow for turbine passed juveniles, 8% of inflow for downstream bypass passed juveniles, 10% of inflow for spill passed juveniles, and 22% of inflow at the time of entry into the downtown canal system for three tagged juvenile alosines. Passage via the downstream route with the greatest proportion of flow at the time of passage occurred 65% of the time. A listing

of route discharge at the time of downstream passage for each juvenile alosine is provided in Appendix E.

5.6 Downstream Transit

A single monitoring station was installed downstream of Lowell for the purpose of detecting radio-tagged juvenile alosines following passage at the Project. That receiver (Station 38) was located approximately 2.1 miles downstream of the project. The minimum, maximum, and quartile transit times through that reach are presented in Table 5-8 and Figure 5-10. The median transit time durations for tagged juvenile alosines moving downstream of Lowell was 6.2 hours (range = 1.0 hours to 1.8 days) for the 2.1 mile downstream reach.

5.7 Proportional Hazard

A total of 145 Pawtucket Gatehouse and 126 E.L. Field Powerhouse forebay events were defined based on recorded detections of juvenile alosines during the 2019 study to evaluate the impact of operational parameters on passage success. The median event duration recorded for radio-tagged juvenile alosines was 4.6 minutes for individuals in the detection field of Station 26 immediately upstream of the Pawtucket Gatehouse and 47 seconds for individuals in the detection field of Station 30 covering the area immediately upstream of the intakes to the downstream bypass and turbine units at the E.L. Field Powerhouse.

5.7.1 Pawtucket Gatehouse

The Pawtucket Gatehouse model failed to meet the criteria necessary to accept the assumption that hazards are proportional (Table 5-10). The water temperature and inflow parameters are not independent of time in this scenario ($p < 0.05$), which means these values may misrepresent the true nature of the relationships with passage success/failure. In addition, the full model also has a p-value less than 0.05, which suggests it may be misrepresenting or masking the relationships between operational variables and rate of passage for juvenile alosines at the Pawtucket Gatehouse. Although results of the Cox proportional hazard model for the Pawtucket Gatehouse are provided in Table 5-9 and illustrated in Figure 5-11, they were not evaluated due to the lack of significance for the full model.

5.7.2 E.L. Field Powerhouse

Results of the Cox proportional hazards model for E.L. Field forebay events suggest a positive relationship between water temperature and the forebay-tailrace head differential versus passage success, decreasing the probability of passage failure by 8% and 7%, respectively (Table 5-11). Despite these marginal impacts, neither water temperature nor the forebay-tailrace head differential were found to be statistically significant in this model. In order to make sure the data met the assumption of proportional hazards and ensure the use of an appropriate modelling framework, inflow and spill were maintained as continuous variables (Table 5-11). Both spill and inflow were found to be insignificant variables with no measurable impact on passage success in the forebay. The only operational variable with a statistically significant impact on the probability of passage failure to depart the E.L Field forebay was combined turbine discharge, which was split into three bins: 592-1980 cfs (i.e., low), 1980-3950 cfs (i.e.,

mid), and 3950-5930 cfs (i.e., high). As illustrated in Figure 5-12, the low generation condition was used as a reference for the mid and high generation conditions. Results suggest a strong, statistically significant interaction between the mid and high generation conditions in relation to passage failure from the E.L. Field forebay. Mid-levels of turbine discharge (1980 and 3950 cfs) increased the probability of passage failure from the E.L. Field forebay by 605%, while high levels of turbine discharge (3950-5930 cfs) increased the probability of passage failure from the E.L. Field forebay by 2223%. The E.L. Field forebay model achieved the criteria necessary to accept the assumption that hazards are proportional (Table 5-12).

5.8 Manual Tracking

In addition to the continuous monitoring provided by the 10 stationary receivers installed throughout the Project area for duration from early October through mid-November 2019, a total of 21 manual detections representing 13 individuals were recorded between October 21 and November 7. Manual tracking for radio-tagged juvenile alosines was most effective via foot and in the vicinity of Project structures (i.e., bypassed reach, tailrace, Northern Canal/forebay). Appendix C contains a listing of manual detections identified to those relative locations and classified as “Transit” for individuals which were subsequently detected at stationary receivers downstream of their manually determined position or “Stationary” for individuals which were not detected again at stationary receivers downstream of their manually determined position(s). The majority of detections were classified as stationary as indicated by a lack of future downstream detections. Two individuals were detected within the Northern Canal downstream of the Pawtucket Gatehouse prior to their eventual downstream passage at the Project (as determined by the stationary receiver data).

6 Summary

An evaluation of the potential impacts on the outmigration of juvenile alosines was conducted in support of the FERC relicensing of the Lowell Project on the Merrimack River. Downstream passage route utilization was evaluated using radio-telemetry during the 2019 fall migration season (October 9 to November 12, 2019). Monitoring of outmigrating juvenile alosines focused on the evaluation of the residence time immediately upstream of the Pawtucket Dam and prior to passage as well as passage route utilization at the Project.

A total of 145 juvenile alosines were tagged and released at mid-river locations approximately one mile upstream of the Pawtucket Gatehouse. Their subsequent downstream arrival and passage at the Project was monitored via a series of fixed-location telemetry receivers within the Lowell Project area. All of the juvenile alosines utilized for this study were collected from Turtletown Pond in Concord, New Hampshire and ranged in total length from 125-144 mm. Radio transmitters were bonded to small fish hooks and then externally affixed to each individual prior to their release. Releases of radio-tagged juveniles were spread over a 16 day period between October 9 and 24.

Upon initial detection at the Pawtucket Dam, the median duration of time spent immediately upstream of the dam structure was 1.3 days with 42% passing downstream within the first 24 hours of their initial detection. Closer examination of the total residence time for radio-tagged juvenile alosines indicated that all individuals determined to have entered the Northern Canal passed through the Pawtucket Gatehouse in less than 30 minutes. Upon entry into the Northern Canal, the median residence duration prior to downstream passage was longer (22.0 hours; range = 0.2 hours to 4.7 days). Nearly 70% of all downstream passage events for radio-tagged juvenile alosines occurred within 48 hours of initial detection in the E.L. Field forebay. The Cox proportional hazards model suggested a statistically significant interaction between the mid and high generation conditions in relation to passage failure from the E.L. Field forebay. The presence of higher generation flows increased the probability that a radio-tagged individual would approach downstream passage options in the power canal (i.e., turbines or downstream bypass) and reject the passage attempt relative to lower generation flows.

Outmigrating juvenile alosines encountering the Pawtucket Dam can (1) pass through the Pawtucket Gatehouse and enter the power canal, (2) pass downstream over Pawtucket Dam via spill, or (3) enter the Pawtucket Canal and navigate downstream via the downtown canal system. Individuals which enter the Northern Canal can subsequently pass downstream via one of the two turbine units at the E.L. Field Powerhouse, utilize the downstream bypass, or pass via the surge gate (operated only in the event of a station trip). During the 2019 evaluation the majority of radio-tagged individuals passed through the Pawtucket Gatehouse and approached the E.L. Field powerhouse. Of the individuals which approached the E.L. Field powerhouse and had a known downstream passage route, 83% eventually passed downstream via the turbine units[4]. Use of the existing downstream bypass system is estimated at 17%. The existing

[4] Note that downstream passage survival for juvenile alosines will be assessed as part of the desktop based *Fish Passage Survival Study*. Downstream passage survival was not estimated for radio-tagged juvenile alosines as part

downstream bypass at Lowell was last assessed for the effectiveness of passing juvenile alosines during 1994 and effectiveness was estimated at 37% during that study (Normandeau 1995). Only two percent of all radio-tagged juvenile alosines were determined to have entered the Pawtucket Canal and attempted downstream passage via the downtown canal system. Of the three individuals which entered the downtown canal system, one was determined to have exited the canal system and was detected downstream at Station 38.

7 Variances from FERC-Approved Study Plan

The FERC-approved RSP indicated that a total of 150 radio-tagged juvenile alosines. Five of the transmitters purchased for this study could not be activated. As a result, a total of 145 radio-tagged juvenile alosines were released and assessed for downstream passage at the Project. There were no additional variances from the FERC-approved study plan.

Appendix D. Responses to September 30, 2020 Revised ISR meeting comments.

Comment No.	Agency	Comment	Response
1	FERC	Can Boott provide a Microsoft Excel file of station operations for the study period to allow for calculation of flow proportions by passage route?	Hourly operations records have been provided in Microsoft Excel format and include values for headpond elevation, forebay elevation, tailrace elevation, inflow, Unit 1 discharge, Unit 2 discharge, downstream bypass discharge, upstream fishway flow, downtown canal flow, and spill flow. The reported station operations at the time of downstream passage for each radio-tagged fish were identified. Section 5.5 of the final report has been modified to include a summary of the proportional volume of discharge through the selected passage route relative to non-selected routes (e.g., if a fish passed downstream via the turbines values reported for that individual would include the volume of water passing through the turbines vs. the volume of water passing downstream via alternative routes (i.e., downstream bypass or spill).
2	NMFS	Table 5-1 in Section 5-1 summarizes the percentage of inflow records from the 2019 study period categorized by volume as well as the percentage of time that each volume category is historically exceeded for the months of October and November. Is it possible to consider the study months of October and November as a	Section 5-1 has been updated to include an examination of Merrimack River conditions during the full October 9 – November 30, 2019 study period relative to flow exceedance probabilities.

		whole to classify the full study period by flow condition?	
3	MDFW	The Cox proportional hazards model for the Pawtucket Gatehouse failed to meet the criteria necessary to accept the assumption that hazards are proportional. Was a principal components analysis type approach considered to create new uncorrelated variables to increase interpretability of the data at that location?	The proportional hazards model for juvenile alosines at the Pawtucket Gatehouse was revisited and a variance inflation test (VIF-test) was conducted on all variables included in the original model. However, no two variables were found to be significantly correlated enough to consider removing or incorporating into an interaction term in the final model. As a result, no modifications were made to the model presented in the Revised ISR report.
4	MDFW and NMFS	In their Revised ISR comment letters both MDFW and NMFS commented: *The goal of the juvenile alosine and American eel downstream passage assessments was to determine the Lowell Project's impact on the outmigration of juvenile alosine and adult American eel. The specific objectives included assessing rates and delay to migration for alosine and evaluation of route specific mortality for American eel. Operation of turbine units in the downtown canal system did not occur during the study for safety reasons. This lack of operation significantly affects the study results and our ability to assess project related impacts. However, it is our understanding that the canal units will be decommissioned, as stated by CRP during a conference call with us and the US Fish and Wildlife Service on November 16, 2020.*	As stated in the DLA, Boott has elected to decommission the downtown canal units, and to remove the units and associated canal infrastructure from the new license.

		Decommissioning of the canal units should be confirmed in the Draft License Application. If confirmed, then additional evaluation of project impacts related to the canals are not necessary. However, is there is a change in this decision and the downtown canal units are part of the proposed action within the Draft License Application, then the agencies intend to request a second year of study once the canal units are fully operational to determine post-spawned adult alosine and American eel downstream migration route selection, passage efficiency, and residence duration associated with the power canal under various operational conditions, including a range of spill conditions.	

Appendix E. Project inflow and discharge by potential passage route at the time of downstream passage for radio-tagged juvenile alosines at Lowell.

1 Introduction

To support the relicensing of the Lowell Hydroelectric Project (Lowell or Project), a desktop review to assess the potential survival of fish passing downstream through turbine units associated with the Project was performed. This Fish Passage Survival Study was identified in the Revised Study Plan (RSP) submitted by Boott Hydropower, LLC (Boott) to the Federal Energy Regulatory Commission (FERC) on January 28, 2019. The approach and methodology described in the RSP for the Fish Passage Survival Study was approved without modifications by FERC in its Study Plan Determination (SPD) letter dated March 13, 2019. The January 28, 2019 RSP indicated that Project turbines in the E.L. Field, Bridge Street, Hamilton and John Street powerhouses would be evaluated as part of the Fish Passage Survival Study. Boott has indicated that Final License Application for the Project (due to FERC by April 30, 2021) will exclude the Bridge Street, Hamilton and John Street stations as part of the Project in the future license. As a result, this report was prepared on behalf of Boott to provide a description of the objectives, methodologies and results of the desktop based fish passage survival evaluation to characterize potential effects to outmigrating diadromous fish species associated with the two turbine units housed in the E.L. Field powerhouse on the mainstem of the Merrimack River.

2 Study Goals and Scope

2.1 Goals and Objectives

The goal of this study was to assess the potential survival of fish passing downstream through the E.L. Field turbines and to inform estimates of Project passage survival for emigrating diadromous fish species (adult and juvenile American shad, river herring, and American eel). Specific objectives for this study were to:

- Assess the potential for impingement for the target species and life stages;
- Assess the potential for entrainment for target species and life stages;
- Conduct a desktop survival analysis to estimate passage survival of target species and life stages for each active turbine type; and
- Assess total Project survival for the target species and life stages.

2.2 Scope

This Fish Passage Survival Study provides the following:

- A description of the Project reservoir, intake structure, turbine units, and operational regime;
- A summary of available fisheries information recently collected within the Project area as well as a summary of recent diadromous fish species returns to the Project;
- An overview of the life history and habitat requirements for three target fish species identified in the RSP (i.e., American shad, river herring, and American eel);

- An assessment of impingement and entrainment potential as a function of (1) the existing rack spacing, (2) calculated approach velocities, (3) the physical dimensions of target fish species, and (4) the swim capabilities (i.e., burst speed) of target fish species;

- A review of information contained in the 1997 Electric Power Research Institute (EPRI) database to provide a summary of (1) the size class composition of target fish species, (2) entrainment densities of target fish species, and (3) calculated survival rates of target species for the subset of hydroelectric projects comparable to the Project;

- The calculation of site-specific turbine passage survival rates for target fish species using the USFWS Turbine Blade Strike Analysis Tool (TBSA); and

- The use of recently collected, species-specific, proportional route selection data to calculate an estimate of total project survival.

3 Methods

This study addresses the qualitative classification of impingement, entrainment, and the probability of turbine passage survival at the Project using a review of relevant biological criteria and physical Project characteristics for three diadromous fish species. Factors that can influence the potential for impingement or entrainment at a hydropower project include structural characteristics such as the size and depth of the intake structure, the velocity of water as it enters the intake structure, the location of the intake structure relative to fish habitat, and the biological and behavioral characteristics (e.g., size, movement or migration patterns, and habitat preferences) of the specific life stages of fish species of interest. The likelihood of impingement is also highly dependent on the physical features and water velocities found at or near the trash racks along with species-specific physiological capabilities (i.e., swim speed). Turbine survival rates are primarily affected by engineering factors such as the amount of head differential of a turbine, its number of blades, rotational speed, hydraulic capacity, and the length of an entrained fish.

3.1 Project Impoundment, Intake, and Turbine Description

The first step in the evaluation of the potential for fish impingement and entrainment was to describe the physical features of the impoundment, E.L. Field intake structure, and turbine units that will affect entrainment, impingement and turbine passage survival. Project dimensions were obtained from available engineering drawings of the Project. Tables 3-1 and 3-2 summarize pertinent Project and turbine parameters and are further described in Section 4.1.

3.2 Life History and Habitat Requirements of Target Fish Species

A description of the life history, habitat requirements, and behavior of fish species was compiled to determine the likelihood of presence near the Project intakes and to evaluate entrainment potential. The “Traits Based Assessment” of Čada and Schweizer (2012) was used to qualitatively assess the potential entrainment risk for fish species, which considers each

species' primary location within the Project, preferred habitat, local movements and reproductive strategy. Species-specific behavioral requirements determine if and when a given life stage interacts with intake operation. The potential for each species to be susceptible to entrainment can be determined based on their life history characteristics in relation to the location of the Project's intake structure.

Categories of entrainment potential based on the likelihood that a fish species/life stage will be located near the intake structures are described as:

- None - species/life stage (e.g., adult, spawning, or juvenile) are not known to prefer the habitat near the intake structures
- Minimal - species may only occasionally be found occupying the habitat near the intake structures
- Moderate - species routinely or seasonally found occupying the habitat near the intake structures
- High - species likely to be found occupying the habitat near the intake structures

3.3 Entrainment Potential of Target Fish Species

The distance between bars on a trash rack (i.e., clear spacing) can affect the likelihood of an individual fish being excluded from moving through the trash rack and entering the turbine intakes. Fish species and life stages with a body width greater than the clear spacing are physically excluded from passing through a trash rack and becoming entrained. Proportional estimates of body width to total length (scaling factor) were compiled by Smith (1985) for a suite of fish species. These species-specific scaling factors were used to determine the minimum length of each species excluded from the turbines by the intake trash rack spacing. The clear spacing values were divided by the scaling factors to calculate the minimum length for each target species that would be excluded at the Project.

3.4 Electric Power Research Institute (EPRI) Entrainment Database Review

The Electric Power Research Institute (EPRI) 1997 entrainment database provides results from entrainment field studies conducted at 43 hydroelectric facilities east of the Mississippi River using full-flow tailrace netting. The database contains site characteristics of each of these facilities, as well as the total number of individuals of each species collected at each of the sites. The species counts are separated into variable size classes ranging from 2 to 30 inches.

A comparison of the EPRI entrainment database was made to provide a literature based assessment to compare with potential entrainment at the Project. To do so, the EPRI database was filtered for characteristics that match or are within a comparable range to those found at the Project which included the following:

1. Plants must be operated in run-of-river mode;
2. Total powerhouse hydraulic capacity must be within ±25% of the existing 6,600 cubic feet per second (cfs) capacity at Lowell (i.e. 4,950 to 8,250 cfs);

3. Trash rack clear spacing must be equal to or greater than the existing 7.25 inch rack spacing at Lowell; and
4. Entrainment data for fish species being considered at Lowell (i.e., American shad, river herring, and American eel) must be available.

Assuming one or more comparable projects were available from the EPRI database, collection totals of the Lowell target species from that set of locations were summarized by size class. In addition, the size class composition of the total number collected was summarized for each target species.

3.5 Impingement Potential of Target Fish Species

The ability for an individual fish to avoid being impinged or entrained at a powerhouse intake often depends on its swimming performance (Castro-Santos and Haro 2005). The swimming performance is directly related to the size of an individual fish; however, the swimming capability also varies among species based on morphological differences. Although there is no standard method that defines how swimming performance is measured, three commonly used definitions or types of swim speed are described in the scientific body of literature for fish (Katopodis and Gervais 2016). The three swim speed types, cruising, prolonged, and burst, are described as the following:

- Cruising or sustained swim speeds can be maintained indefinitely (Bain and Stevenson 1999);
- Prolonged swim speeds can be maintained between 5 and 8 minutes (Bain and Stevenson 1999); and
- Burst (also called startle, darting or sprint) swim speeds can be maintained for less than 20 seconds (Beamish 1978).

Burst swim speeds were used to assess if a fish can adequately escape involuntary impingement or entrainment. If a fish has a greater burst swim speed than the turbine intake approach velocity, it is capable of moving away from the intake flow field to avoid interaction. To assess swimming capabilities for the target fish species of interest, burst swim speeds were compiled from the available scientific literature.

To ascertain whether or not a certain size fish of a particular species is likely to be impinged or entrained, the burst swim speeds were compared to the calculated approach velocity of the intake trash racks at the maximum hydraulic capacity of the Project. The approach velocity at the Project intake was calculated using the velocity equation:

$$V = Q/A$$

Where:
Q = flow rate (cfs);
V = approach velocity (feet per second (fps)); and
A = area (square feet (ft^2)).

Fish species and sizes whose burst swim speeds are less than the approach velocity at the Project intake are susceptible to impingement at the trash racks if their body widths are greater than the trash rack spacing. If the body width of a fish is less than the trash rack spacing and its burst swim speed is less than the approach velocity, it is more susceptible to entrainment.

3.6 Turbine Survival Evaluation

To estimate survival of fish that entrain and pass through Project turbines, theoretical predictions were used to estimate a survival rate using a blade-strike model developed by the Department of Energy (Franke et al. 1997) that uses various turbine, fish and operations characteristics of a hydroelectric project to calculate a turbine blade strike and survival probability. This model was further modified by the United States Fish and Wildlife Service which produced the Turbine Blade Strike Analysis (TBSA) Tool that estimates the fraction of a population of fish that are killed by blade strike passing through a hydroelectric project (Towler and Pica 2018). TBSA creates a normally distributed population of fish described by its number, mean length, and standard deviation of length that are routed through hazards at a hydroelectric project, e. g., a turbine. Monte Carlo simulations are performed to determine the percentage of individuals subjected to turbine blade strike.

The TBSA is informed with turbine parameter values specific to the Project and calculated using methods outlined in Franke et al. (1997). The probability of blade strike in the model is based on several factors, including the number of runner blades, fish length, runner blade speed, turbine type, runner diameter, turbine efficiency, and total discharge. These factors are inputs into the model which predicts survival for a fish of a designated length, regardless of species. The TBSA model was used to predict turbine passage survival estimates expected for each target species in the Project area and up to the maximum lengths (rounded to whole inch) for each target fish species that could entrain through the existing trash rack spacing at the Project. The TBSA model simulations for American shad and river herring were run using a correlation factor (λ) of 0.2 which is the recommended conservative value (Towler and Pica 2018). An interim recommendation from the USFWS Fish Passage Engineering Group suggests the use of λ = 0.4 for American eels based on an analysis which evaluated the effect of varied TBSA correlation factors to adjust modeled estimates to match results from a series of empirical eel passage studies.

3.7 Electric Power Research Institute (EPRI) Turbine Survival Database Review

Similar to the comparison of the EPRI entrainment database review, the EPRI (1997) turbine survival database was reviewed to provide an equitable literature-based comparison of the turbine survival estimates calculated for the Project. To do so, the EPRI database was filtered for characteristics that match or are similar to those found at the Lowell Project. The following characteristics were selected to identify comparable projects:

1. Turbine type must be Kaplan;
2. Turbine hydraulic capacity must be within ±25% of the existing 3,300 cfs capacity at Lowell (i.e. 2,475-4,125 cfs);

3. Head rating must be within ±25% of the existing 39 feet of head at Lowell (i.e. 29 to 49 feet); and
4. Entrainment data for fish species being considered at Lowell (i.e., American shad, river herring, and American eel) must be available.

Assuming one or more comparable projects were identified within the EPRI survival database, the immediate, 24-hour, and 48-hour survival estimates were identified, if available, as they provided a range of time post-turbine passage for evaluating each species.

3.8 Qualitative Assessment of Entrainment and Turbine Survival Potential

Data collected during the literature review and site-specific evaluation process (i.e., habitat and life history, swim speeds, and turbine survival model estimates) were used to compile a qualitative assessment of the potential entrainment of target fishes. The qualitative assessment used a multi-step rank of:

- High (H)
- Moderate (M)
- Low (L)

Desktop impingement and entrainment assessments assigned an overall entrainment potential rank to each of the relevant life stages of target species considered based on consideration of habitat and life history, swim speed relative to intake velocity, and minimum exclusion lengths relative to trash rack spacing. In general, fish with life history attributes that include obligatory downstream migration are given a rating of 'High', while those with juvenile life history stages placing them in the vicinity of the intakes or as adults with swim speeds not necessarily greater than the approach velocity are labeled as 'Moderate' risk. Species with life history attributes that generally keep them away from the intakes or fish that had a burst swim speed greater than the intake velocity are listed as a 'Low' risk for entrainment. In relation to swim speed, regardless of life stage, fish are considered 'High' risk if the maximum burst speed does not exceed the intake velocity, 'Moderate' risk if the intake velocity falls within the range of burst swim speed, and 'Low' risk if the burst swim speed completely exceeded the intake velocity.

The entrainment potential classification for trash rack spacing depended on the minimum body length exclusion results. If the minimum exclusion length for the existing trash rack spacing was longer than the standard length for a juvenile or adult (i.e., many individuals of that species and life stage are likely to be shorter than the minimum exclusion length) it received a "High" entrainment risk potential. A "Moderate" entrainment risk potential was applied when the minimum exclusion length overlapped with a portion of the individuals that would be expected to achieve that length by the life stage indicated. A "Low" entrainment risk potential was applied when the minimum exclusion length of a trash rack was less than the standard length of the life stage being considered.

The risk categories for the turbine survival potential were based on the TBSA model estimates. TBSA results were converted to a qualitative ranking system similar to Winchell et al. (2000) for

standard lengths of the juvenile and adult life stages. “High” survival potential was applied to estimates greater than 95%, “Moderate” for estimates between 85-95%, and “Low” for estimates less than 85%.

Table 3-1: Lowell Project impoundment and intake characteristics

Site Characteristic	Lowell Project

4 Results

4.1 Lowell Project Description

4.1.1 Project Location and Facilities

The Lowell Hydroelectric Project (Project) is located at the Pawtucket Dam on the Merrimack River in the City of Lowell in Middlesex County, Massachusetts. The Project is located approximately 11 miles upstream of the Lawrence Project (FERC No. 2800) and approximately 30 miles downstream of the Amoskeag Dam (a development of the Merrimack River Project, FERC No. 1893) in New Hampshire. The 116-mile-long Merrimack River begins at the confluence of the Winnipesaukee and Pemigewasset Rivers in Franklin, New Hampshire; flows southward into Massachusetts; and then travels northeast until it discharges into the Atlantic Ocean. The Project includes a single powerhouse, the 15.0-megawatt (MW) Eldred L. Field (E.L. Field) powerhouse constructed in 1985-1986 during Project redevelopment. The total installed capacity of the project is 15,012 kW.

The E.L. Field powerhouse utilizes the existing Pawtucket Dam and the first 2,200 feet of the Northern Canal. The powerhouse is located close to the canal, downstream of the University Avenue Bridge (also called the Moody Street Bridge), with an intake structure drawing water from the Northern Canal. A 440-foot tailrace channel, surge gate and fish passage facilities comprise other major E.L. Field powerhouse features.

The Project also includes the Guard Lock and Gates Facility ("Guard Locks") and the approximately 1,600-foot-long portion of the Pawtucket Canal leading from the Project impoundment to the Guard Locks.

4.1.2 Impoundment Characteristics

The Project operates in a run of river mode and has no usable storage capacity. The pond formed by the Pawtucket Dam extends approximately 23 miles upstream to Moore's Falls in Litchfield and Merrimack, New Hampshire. At the normal pond elevation of elevation of 92.2 feet NGVD 29 (crest of pneumatic crest gate), the surface area of the pond is reported to encompass an area of about 720 acres. The gross storage capacity between the normal surface elevation of 92.2 feet NGVD 29 and the minimum pond level of 87.2 feet NGVD 29 is approximately 3,960 acre-feet.

4.1.3 Powerhouse, Intake Structure, and Trash Racks

The E.L. Field powerhouse is a reinforced concrete structure. The powerhouse is approximately 109-feet-long by 96-feet-wide and houses two generating units with a total authorized generation of 15.0 MW. Each intake is equipped with trash racks with a clear spacing of 7.25 inches. Each unit intake rack covers an area of 1,034.72 ft^2. The powerhouse incorporates a separate conventional intake structure for each of the station's two identical units. Each intake is equipped with trashracks; intake and draft tube gate slots with permanent or bulkhead style gates for emergency shutdown and dewatering purposes are also provided. The powerhouse is equipped with a traversing trash rake to remove debris at the intake.

4.1.4 Downstream Bypass

The downstream fishway at the powerhouse consists of an adjustable-flow sluiceway and bypass adjacent to the intake headwall. Downstream migrants entering the bypass are quickly sluiced into an enlarged and deepened plunge pool located in the bypassed river reach next to the powerhouse. Natural channel braids in the riverbed allow emigrants to move downstream to the mainstem of the river, at the confluence of the river reach and tailrace.

4.1.5 Turbines

The Lowell Project includes two identical horizontal Kaplan turbines housed in the E.L. Field powerhouse with a total installed generating capacity of 15.0 MW. Each unit has a maximum hydraulic capacity of 3,300 cfs. See Table 3-2 for unit specifications.

4.1.6 Project Operations

The Project is operated in a ROR mode using the automatic pond level control capability of the E.L. Field Powerhouse. Boott normally operates the Project to maximize flow through the available units at the E.L. Field Powerhouse, then routes any additional flows through the Pawtucket Canal system. When river flows exceed the hydraulic capacity of the E.L. Field units (approximately 3,300 cfs per unit or 6,600 cfs for both units), excess flows up to approximately 2,000 cfs are routed through the downtown canal system. Any flows in excess of approximately 9,000 cfs are passed over the Pawtucket Dam spillway. The Project is required to maintain a minimum flow equal to 1,990 cfs or inflow, whichever is less, as measured immediately downstream from the Project.

4.2 Life History and Habitat Requirements of Target Fish Species

The Merrimack River watershed is home to a diverse assemblage of approximately 50 species of fishes, including cold water and warm water species, diadromous species, and introduced gamefish and non-gamefish species. The Fish Assemblage Study, conducted by Normandeau during the spring, summer and fall of 2019, consisted of boat electrofishing and gill net sampling to characterize the fish community in the Project impoundment. When all sample locations and gear types are considered, a total of 1,847 individuals representing twenty-two fish species were collected from the Lowell impoundment during 2019. The majority of fish collected were resident fish species with centrarchid and cyprinid species being most abundant. A summary of the fish captured in the 2019 study is provided in Table 4-1.

Diadromous species inherently have the highest likelihood of direct interaction with the Project as they are obligatory migrants which require passage upstream and downstream at the Project to complete their life cycles. Observations of diadromous species upstream of the Lowell Project during the Fish Assemblage Study were limited to observations of juvenile alewives during the summer and fall sampling events as well as a limited number of juvenile American eels during the three seasonal periods. Despite limited observations of diadromous fish species during the Fish Assemblage Study, American shad and river herring are documented annually utilizing the upstream passage facilities at the Project (i.e., the E.L. Field fish lift and Pawtucket Dam fish ladder). Camera-based counts of diadromous fish returns at Lowell conducted

annually since 2018 are summarized in Table 4-2. For the period 2018-2020, an annual average of 8,232 American shad and 179,239 adult river herring have volitionally passed upstream of the Project. In addition, Boott has quantified upstream passage of juvenile American eels since 2014. A total of 974 individuals were passed upstream during the 2020 passage season. Due to their migratory requirements and presence in the Project area, the target species for this analysis included American shad, river herring (i.e., alewife and blueback herring), and American eel.

4.2.1 American Shad

American shad are an anadromous, highly migratory, coastal pelagic, schooling species that range from northern Labrador to Florida. They are the largest member of the herring family (Clupeidae), and females are larger than males at all ages. Mature male shad range from 12 to 17.5 inches (30.5 - 44.7 cm) and mature females range from 15 to 19 inches (38.3 - 48.5 cm) (Stier and Crance 1985). Males mature at age 4, while females mature at ages 5-7. The maximum age is 11 years. Spending the majority of their life in the sea, mature adults migrate upriver to natal rivers to spawn from May to July. Although shad spawn in freshwater, there is no apparent required distance upstream of brackish water (Stier and Crance 1985). American shad return downstream to marine waters soon after spawning. American shad are known to be prolific spawners, with females producing up to 600,000 eggs. After broadcast-spawning, fertilized eggs sink to the bottom, where they become lodged in rubble and water-harden. Hatching typically occurs after 1-2 weeks, dependent on water temperature. Larvae may remain in freshwater, or drift into brackish water and grow rapidly, transforming into juveniles approximately 4 to 5 weeks after hatching (Stier and Crance 1985). During the first fall of their life, juvenile shad leave fresh water and migrate in schools downstream to the sea. Upon reaching the ocean, they become long-range coastal migrants. While at sea, American shad form large schools and migrate vertically to feed on zooplankton.

Period and life stages of greatest likelihood of exposure to intakes at the Lowell Project:

- June-July: Following spawning at upstream locations, adult American shad migrate downstream to return to marine habitat
- September-October: Following time spent in upstream rearing habitat, juveniles migrate downstream to enter marine habitat.

4.2.2 River Herring (Alewife and Blueback Herring)

Alewife and blueback herring are clupeid species very similar in appearance and behavior. Since it is difficult to distinguish between the two species, they are frequently considered together under the collective term “river herring”. They are anadromous, euryhaline, coastal, and pelagic fish (Bigelow and Schroeder 1953, Cooper 1961, Collette and Klein-MacPhee 2002). Alewife range from the St. Lawrence River, Canada to North Carolina (Neves 1981), and mature between ages 3-6, and are typically 10 to 11 inches (250-280 centimeters (cm)) in length (Bigelow and Schroeder 1953). They form large schools during their spring spawning migrations from the ocean to coastal rivers. Spawning migrations occur in a south-to-north progression as

water temperatures warm in the spring, typically taking place in late April to mid-May in the Gulf of Maine (Bigelow and Schroeder 1953). Blueback herring have a greater geographical range than alewife, ranging from Cape Breton, Nova Scotia to Florida. They also spawn in early June in the Gulf of Maine, roughly four weeks later in the season than alewife. Similar to alewife, blueback herring mature between the ages of 3-6 years. Adults require little or no current for spawning, utilizing ponds, lakes, or slow-flowing riverine areas at water temperatures of 13° to 20°C (55° to 68° F) (Otto et al. 1976, Wyllie et al. 1976, Kellogg 1982). There appears to be little preference for sediment type as spawning has been observed over hard sand, gravel, stone, detritus-covered bottoms and among sticks and vegetation (O'Dell 1934, Havey 1961). Eggs are about 1 millimeter (mm) in diameter, adhesive, and require 3 to 6 days to hatch over a temperature range of 16° to 22° C (61 to 72 °F). Larvae hatch at 0.1 to 0.2 inches (3 to 5 mm) in total length and become juveniles at approximately 0.8 inches (20 mm; Cianci 1969).

River herring have declined in recent years. The Atlantic States Marine Fisheries Commission reports that river herring stocks are depleted to near historic lows along the Atlantic coast (ASMFC 2012).

Period and life stages of greatest likelihood of exposure to intakes at the Lowell Project:

- May-June: Following spawning at upstream locations, adult river herring migrate downstream to return to marine habitat

- September-October: Following time spent in upstream rearing habitat, juveniles migrate downstream to enter marine habitat.

4.2.3 American Eel

The American eel is a catadromous species common in rivers, streams, lakes, tidal marshes and estuaries throughout the Northern Atlantic. It is native to Atlantic coastal waters from Newfoundland to South America. Males typically reach sizes up to 24 inches (61 cm) in length, while females reach larger sizes of 30 to 40 inches (76 to 102 cm). They are a long lived species, able to reach up to 30 years of age. Eels spend the majority of their lives in fresh water, but upon reaching maturity, they descend to the Atlantic Ocean in the fall. They migrate to the Sargasso Sea and spawn in February to April, dying shortly after. Females are prolific egg producers, with one female producing up to 20 million eggs. After spawning, leptocephalus larvae drift at sea for up to a year, and are gradually transported north by the Gulf Stream. As they approach the North American coast, the larvae metamorphose into unpigmented juveniles known as glass eels. During this metamorphosis, the body becomes cylindrical, the jaw and head are altered and the digestive tract becomes functional (Collette and Klein-MacPhee 2002). Glass eels appear in southern New England in March at 2 to 4 inches (~ 50-100 mm) in length. They migrate upstream at night into freshwater where they feed, and become pigmented; this is known as the "elver" life stage. They grow slowly until they sexually mature, which can take up to 20 years. However, eels are known to reach maturity as small as 11 inches (28 cm) for males and 18 inches (46 cm) for females. Once sexual maturity occurs in late summer to early

fall, the eel begins moving downstream, the eyes and pectoral fins enlarge, and feeding stops (Collette and Klein-MacPhee 2002). Specific spawning migration routes and egg life history information are currently unknown.

Period and life stages of greatest likelihood of exposure to intakes at the Lowell Project:

- September-November: Adult "silver" eels migrate downstream to begin spawning migration to the Sargasso Sea.

Table 4-1. Number of fish captured upstream of Pawtucket Dam by boat electrofishing and experimental gill net during spring, summer and fall sampling, 2019

Common Name	Spring	Summer	Fall	2019

Net Upstream Passage at Lowell Project			
Year	River Herring	American Shad	American Eel
2018	311,867	14,046	49
2019	43,871	2,201	2
2020	181,979	8,450	2

4.3 Entrainment Potential of Target Fish Species

Minimum exclusion lengths for juvenile and adult migrant life stages for the existing trash rack clear spacing at the Lowell Project are presented in Table 4-3. Proportional estimates of body width to total length (scaling factor) collected from Smith (1985) were used to determine the minimum length of each target species that would be excluded from entraining through the trash racks present at the Lowell Project (minimum exclusion size = rack clear spacing/scaling ratio).

All of the calculated estimates yielded lengths for target species that are unlikely to be present in the Project (i.e., a length outside of the range expected for the species in the vicinity of the Lowell Project). For example, the minimum size of American shad predicted to be excluded by a 7.25-inch intake rack is 54.1 inches—a length not attained by this species. In all cases where the maximum size of the species did not exceed the minimum exclusion size, a designation of 'none' was applied (Table 4-3). The existing 7.25 inch clear rack spacing will not physically exclude target fish species considered for this evaluation from entrainment at the E.L. Field powerhouse

Table 4-3. Minimum length for target fish to be excluded from entrainment based on existing 7.25 inch trash rack spacing

Common Name	Scaling Factor for Body Width[1]	Typical Length (inches) for target species juveniles and adults potentially encountered at the Project		Calculated Minimum Exclusion Length (inches)*
American shad	0.134	Juvenile	2-6[1]	none
		Adult	15-23[2]	
River herring	0.105	Juvenile	1.5-6[1]	none
		Adult	9-13[3]	
American eel	0.037	Adult	25-41[4]	none

* "None" indicates that the calculated exclusion length exceeds the maximum length expected for the species at Lowell

1 Upper end of range based on 145 juvenile alosines handled as part of the Juvenile Alosine Downstream Passage Assessment; Lower end of range adopted from species review

2 Based on 544 adult American shad handled as part of the Upstream and Downstream Adult Alosine Passage Assessment

3 Based on 914 adult river herring handled as part of the Upstream and Downstream Adult Alosine Passage Assessment

4 Based on 162 adult eels handled as part of the Downstream American Eel Passage Assessment (Note Soucook River origin eels ranged 27-34 inches; St. Croix River origin eels ranged 24-41 inches)

4.4 Electric Power Research Institute (EPRI) Entrainment Database Review

The EPRI 1997 database was reviewed for comparable hydroelectric projects using the criteria presented in Section 3.4. Following exclusion of project locations with differing operational styles (i.e., not run-of-river) or capacities differing from Lowell by ±25%, a single location was identified (Table 4-4). Although the operating mode and total powerhouse capacity were comparable, the rack spacing at the Wisconsin River Diversion (2.2 inches) was considerably less than the relatively wide rack spacing present at Lowell (i.e., 7.25 inch clear spacing). Lacking a set of comparable hydroelectric projects, a qualitative comparison of existing entrainment data was not conducted as part of this Lowell analysis.

Table 4-4. Hydroelectric facilities identified within the EPRI (1997) entrainment database considered for comparison to the Lowell Project

Facility Name	Total Plant Capacity (cfs)	Operating Mode	Trash Rack Spacing (in)
Wisconsin River Division	5,150	ROR	2.2
Lowell	6,600	ROR	7.25

ROR = Run-of-river

4.5 Impingement Potential of Target Fish Species

A summary of burst swim speeds determined for adult and juvenile American shad and river herring and adult American eel is presented in Table 4-5. These data were obtained using the Swim Speed & Swim Time Tool[1] (Katopodis and Gervais 2016; Di Rocco and Gervais 2020). The expected size range for each species/life stage was evaluated relative to the data available in the Swim Speed & Swim Time Tool and five representative lengths were chosen for burst speed estimation from the database. For each species/life stage, the five representative lengths included the upper and lower bounds of the anticipated size range for the Project area as well as the 25th, 50th, and 75th percentile lengths within that range. Each unique species-length combination was input into the Swim Speed & Swim Time Tool and produced a relationship for swim speed and swim time for a particular body length. For each body length selected to be assessed for each species, the following estimates were recorded:

1. Speed (ft/s) achieved by 97.5% of individuals of species X at body length Y for 3 seconds;
2. Speed (ft/s) achieved by 87.5% of individuals of species X at body length Y for 3 seconds;
3. Speed (ft/s) achieved by 50% of individuals of species X at body length Y for 3 seconds;

[1] Available online at: http://www.fishprotectiontools.ca/speedtime.html

4. Speed (ft/s) achieved by 12.5% of individuals of species X at body length Y for 3 seconds; and

5. Speed (ft/s) achieved by 2.5% of individuals of species X at body length Y for 3 seconds.

It is understood that burst swim speeds may vary greatly among different fish species as well as among sizes of the same species. However, variation exists within individuals of the same species and size class. Katopodis and Gervais (2016) demonstrate ascending physical capabilities as a smaller portion of the test fish are represented by each speed rating. For example, 97.5% of Adult American shad in the 15 inch size class are expected to be capable of achieving a speed of 17.3 fps for a period of 3 seconds, while only 2.5% of American shad of the same size are expected to be able to achieve a speed of 26.8 fps for 3 seconds. For the purposes of this desktop evaluation values representing the 50^{th} percentile of swim speed over a three second period were selected as representative of a fishes burst swim capability. The 50^{th} percentile speed rating for the minimum, median, and maximum size of each of the target fish species and life stages is provided in Table 4-5. The full range of swim speed estimates for target fish species generated using the Swim Speed & Swim Time Tool are provided in Appendix A.

Figure 4-1 presents the estimated burst speeds for the target species and life stages relative to the calculated intake velocity under full generation at the E.L. Field powerhouse intake structure (3.2 fps). In general, target species whose burst swim speeds are less than the approach velocity at an intake are likely to be involuntarily impinged or entrained depending on the size of an individual and the intake rack spacing. Burst speeds for each of target species/life stages considered in this assessment that are in excess of the calculated intake velocity at the E.L. Field powerhouse suggests the potential for involuntary impingement or entrainment is low. Individuals with burst speeds less than the approach velocities at E.L. Field are more likely to be entrained than impinged as most will fit through the existing rack spacing of 7.25 inches (Section 4.3).

Table 4-5. Burst swim speed information compiled from scientific literature for target fish species

Common Name	Size potentially encountered the region (in)	Size included in burst speed estimate based on data availability	Burst Speed (fps) at minimum size[5]	Burst Speed (fps) at median size[5]	Burst Speed (fps) at maximum size[5]
American shad (Juv)	2-6[1]	2-6	5.2	8.4	11.2
American shad (Adult)	15-23[2]	10-15	16.2	19.0	21.5
River herring (Juv)	1.25-6[1]	1.25-6	3.6	7.8	11.2
River herring (Adult)	9-13[3]	9-12	15.1	16.7	18.4
American Eel	25-41[4]	21-45	11.0	14.9	18.4

4.6 Turbine Survival Evaluation

Table 4-6 provides a summary of the calculated TBSA turbine survival estimates for alosines (i.e., American shad and river herring) entrained through the E.L. Field Kaplan units. Survival values were estimated for the range of body lengths anticipated to be prone to entrainment based upon the minimum exclusion sizes presented in Table 4-3 as well as reasonable lengths expected to occur within the Project area. Estimates of turbine passage were inversely related to body length for each species/life stage considered with highest survival estimated for small juvenile shad or herring at 2 inches of length (~99%) and the lowest for adult American shad approaching 25 inches of length (~83%). A separate TBSA model was assembled for American eel which relied on recent USFWS guidance on the use of a varied correlation coefficient for that species (Table 4-7). The estimated range of survival for eels passing downstream through the E.L. Field turbines ranged from 71-39%. Similar to the trend observed for alosines, the rate of survival for adult eels was predicted to decrease as body size/length increased.

Table 4-6. TBSA predicted survival estimates for adult and juvenile American shad and river herring at the E.L. Field powerhouse.

Species/Life Stage	Size potentially encountered the region (in)	Body Length (Inches)							
		2 in	4 in	6 in	8 in	12 in	16	20	25
American shad (Juv)	2-6	98.6%	97.2%	95.9%					
American shad (Adult)	15-23						89.0%	86.4%	83.1%
River herring (Juv)	1.5-6	98.6%	97.2%	95.9%					
River herring (Adult)	9-13				94.8%	91.8%	89.0%		

Assumes full generation; λ = 0.2

Table 4-7. TBSA predicted survival estimates for adult American eels at the E.L. Field powerhouse.

Species/Life Stage	Size potentially encountered the region (in)	Body Length (Inches)						
		21	24	28	32	36	40	45
American eel (Adult)	25-41	71.2%	67.3%	61.8%	56.5%	51.7%	46.0%	39.1%

Assumes full generation; λ = 0.4

4.7 Electric Power Research Institute (EPRI) Turbine Survival Database Review

The EPRI 1997 survival database was reviewed for comparable hydroelectric projects using the criteria presented in Section 3.6. Following exclusion of project locations with differing turbine types (i.e., not Kaplan) or turbine unit capacities differing from Lowell by ±25%, a single location was identified (Table 4-8). Although the turbine style and capacity were comparable, the project head at Townsend Dam (16 feet) was considerably less than that at Lowell (i.e., 39 feet). In addition, entrainment survival data for the target species considered in this report were not available at Townsend Dam. Lacking a set of comparable hydroelectric projects, a qualitative comparison of existing entrainment survival data was not conducted as part of this Lowell analysis.

Winchell et al. (2000) provides a review of the EPRI (1997) database and a generalized summary of survival based on turbine type, runner speed, and fish size (Table 4-9). Winchell et al. (2000) reports mean survival rates (all fish species combined) for low speed axial flow (includes Kaplan) units to range from 95.4% for fish ≤ 4 inches to 87.2% for fish between 8 and 12 inches.

Table 4-8. Hydroelectric facilities identified within the EPRI (1997) turbine survival database considered for comparison to the Lowell Project

Facility Name	Turbine Type	Rated Head (ft)	Rated Flow (cfs) Per unit	Speed (rpm)	Runner Diameter (ft)	Runner Blades
Townsend Dam	Kaplan (Horizontal)	16	2,200	152	9.4	3
Lowell	Kaplan (Horizontal)	39	3,300	120	12.7	5

Table 4-9. Summary of fish survival rates by turbine type, speed, capacity and fish body size as compiled by Winchell et al. (2000)

Turbine Type	Runner Speed (rpm)	Hydraulic Capacity (cfs)	Fish Size (mm)	Average immediate survival (all species combined)		
				Minimum	Maximum	Mean
Axial Flow (Kaplan) Winchell (2000)	<300	636-1,203	<100	94.1%	98%	95.4%
		636-21,000	100-199	89.8%	98%	94.8%
		636-2,200	200-299	77.4%	97%	87.2%
		1203-2200	300+	86.8%	100%	93.4%

4.8 Qualitative Assessment of Entrainment and Turbine Survival Potential

Evaluating entrainment potential and subsequent survival for the target fish species required combining and synthesizing the species-specific behavioral traits, life stages, and swimming capabilities and comparing them to the Project's unique intake, water conveyance and infrastructure characteristics. The blending of these factors yielded a qualitative assessment of whether or not a target fish species will potentially entrain through the Project's intakes. In the event a fish becomes entrained, a secondary evaluation of the potential for that individual to survive passage through the Project's turbines depended primarily on its length and the physical parameters associated with the specific turbine. This final qualitative assessment took into consideration and summarized all of the factors that influenced entrainment and turbine passage and is presented in Table 4-10.

When the life history characteristics, behavior, and habitat use are considered, all species considered during this analysis (American eel, American shad, and river herring) are obligatory diadromous migrants. As such, they are required to pass the Project as part of their life cycle resulting in the classification of "high" entrainment potential for that category. All species/life stages considered in this assessment have the potential to become entrained through the existing 7.25 inch spaced racks because their body dimensions will permit them to fit through those openings. When the median burst swim speed rates are considered (Table 4-5), each species/life stage demonstrated potential to evade involuntary entrainment at Lowell. Only a portion of juvenile river herring in the low end of the expected size range for the species at Lowell would be expected to have a burst swim capability weak enough to be unable to avoid involuntary entrainment (Appendix A).

Outmigrating alosines are generally surface oriented as evidenced by their affinity for passing downstream of hydroelectric projects via overflow spillways or bypasses. That behavior may help to reduce the overall entrainment through the E.L. Field turbines at Lowell. Downstream bypass usage was quantified during the 2019 Juvenile Alosine Downstream Passage Assessment and 2020 Upstream and Downstream Adult Alosine Passage Assessment. Of the 99 radio-tagged juvenile alosines entering and passing downstream via the E.L. Field power canal, 17% utilized the existing downstream bypass facility and avoided turbine entrainment. Adult alosines which entered the Northern Canal upstream of the E.L Field intake structure exhibited higher rates of downstream bypass usage with 49% (97 of 200) of adult river herring and 52% (33 of 64) of adult American shad passing via the route.

Adult American eels are generally bottom oriented. Based on that generalized behavior during outmigration, their ability to fit through the existing rack spacing, and the presence of only a surface oriented downstream bypass it is expected that a high proportion of outmigrating eels which enter the Northern Canal upstream of the E.L. Field intake structure will entrain through the turbines. Entrainment of outmigrating silver eels was assessed during the 2019 Downstream American Eel Passage Assessment. During that study, 98.5% of tagged eels (134 of 136) which entered the Northern Canal were entrained at the E.L. Field turbine units.

The majority of individuals approaching the E.L. Field powerhouse are expected to be physically capable of avoiding involuntary entrainment due to their swimming capability relative to the intake velocity. However, it is still likely that individuals may voluntarily become entrained due to their need to migrate downstream to the marine environment. TBSA estimated survival rates for juvenile shad and river herring are expected to be high (>95%) whereas TBSA survival estimates for adults are classified as moderate (85-95%) for river herring to low (<85%) for larger bodied American shad. TBSA estimates of turbine survival for adult silver eels were low (<85%) over the full range of body lengths evaluated.

Table 4-10. Qualitative project passage survival potential for target fish species relative to factors influencing entrainment and turbine survival at Lowell

Species and Life Stage	Entrainment Potential			Survival
	Behavior, Habitat and Life History	Trash rack Clear Spacing	Swim Speed compared to Lowell Units	
		7.25 inches	(3.2 fps)	Kaplan
American Shad				
Juvenile	H	H	L	H
Adult	H	H	L	M-L
River Herring				
Juvenile	H	H	M-L	H
Adult	H	H	L	M
American Eel				
Adult (silver)	H	H	L	L

4.9 Total Project Survival

Empirical estimates of downstream passage survival were collected for adult American eels, river herring and American shad at Lowell during the 2019 Downstream American Eel Passage Assessment and 2020 Upstream and Downstream Adult Alosine Passage Assessment.

When all downstream passage routes are considered, the total project survival for adult American eels was estimated at 75.5% (75% CI = 71.4%-79.6%). An adequate sample size was available to produce a route-specific estimate of downstream passage survival for adult American eels at only the E.L. Field turbines (75.0%; 75% CI = 70.6%-79.4%). The limited number of radio-tagged eels passing the Project via spill (n = 4) or via the downstream bypass system (n = 2) were all determined to have successfully approached the Lawrence Project following downstream passage at Lowell. In the case of adult eels, the TBSA model (Table 4-7) tended to underestimate turbine survival.

When all downstream passage routes are considered for adult river herring, the total project survival at Lowell was estimated at 80.1% (75% CI = 76.7%-83.6%). When examined by passage route, survival was estimated for adult river herring passing through the downstream bypass at 87.8% (75% CI = 81.8%-91.5%) and for adult river herring passing downstream through the E.L. Field turbines at 73.9% (75% CI = 68.8%-79.1%). Similarly, total project survival at Lowell was estimated for adult American shad at 70.0% (75% CI = 64.5%-74.6%). When examined by passage route, survival was estimated for adult shad passing over the Pawtucket Dam via spill at 89.2% (75% CI = 82.6%-93.8%), through the downstream bypass at 82.6% (75% CI = 75.7%-90.9%) and through the E.L. Field turbines at 35.5% (75% CI = 25.8%-45.2%). In the case of adult alosines, the TBSA model (Table 4-6) tended to overestimate turbine survival.

An empirical estimate of juvenile alosine survival was not derived during the 2019 Juvenile Alosine Downstream Passage Assessment at Lowell. As a result, the TBSA desktop tool was used to estimate total project survival for juvenile alosines at the Project. The model required input of available downstream passage routes and an estimate of their proportional usage. Those rates were obtained from the 2019 study which estimated route usage for individuals passing the project via known mainstem routes as 11.6% via spill, 15.1% via the downstream bypass, and 73.2% via the E.L. Field turbine units. These observed route selection probabilities were imported into a multi-route TBSA model to evaluate the predicted whole-station survival for a normally-distributed population of 1,000 3.5 inch (S.D. ±1.0 inches) fish. For non-turbine routes (e.g., downstream bypass or spill), an estimate of passage mortality was required and was based on the empirical estimates obtained for adult alosines at the Project (12% at the downstream bypass and 11% via spill). Turbine-specific parameters were incorporated as previously described above in Table 3-2. Using this methodology, total project survival at Lowell for juvenile alosine-sized fish is estimated at 94.8%. Passage failures were attributed to fish passing downstream via the turbines (2.1% of total losses) and the downstream bypass facility/spill (3.1% of total losses).

These estimates of total project survival are all based on flow conditions during the study periods. As identified in the individual study reports the majority of the passage periods for these evaluations could be classified as normal to low flow. It is expected that changes in inflow will influence route selection and subsequently may affect the estimates of total project survival depending on the distribution of individuals among passage routes, each with their own specific passage survival rate.

5 Summary

Interactions with the Lowell Project for each of the species and life stages considered during this assessment are unavoidable based on their obligatory seasonal movements to complete portions of their life cycles. For all three target species (excluding American eel) individuals of both the adult and juvenile life stages are required to pass downstream of the Project in order to complete their life history. For this assessment, American eel was only considered as an entrainment/impingement risk during the adult life stage when they are actively out-migrating. Project interactions for alosines occur most frequently during the spring/early summer when post-spawn adults return downstream and during the fall/early winter when juveniles are migrating to the marine environment. Similar to juvenile alosines, the outmigration period for adult eels occurs during the fall time period.

As each of the target species/life stages are required to pass the Project as part of their life cycle, these species have a high probability of interacting with the E.L. Field turbine which resulted in a classification of "high" for the entrainment potential for that category. All species/life stages considered in this assessment have the potential to become entrained through the existing 7.25 inch spaced racks because their body dimensions will permit them to fit through those openings. When the median swim burst speed rates are considered, each species/life stage demonstrated potential to evade involuntary entrainment at Lowell. Only a portion of juvenile river herring in the low end of the expected size range for the species at Lowell would be expected to have a burst swim capability weak enough to be unable to avoid involuntary entrainment.

A TBSA assessment was conducted for fish lengths representative of (1) the size range of target species likely to be present at Lowell, and (2) body lengths less than the minimum exclusion length which would be subject to entrainment. The TBSA correlation value used in these analyses were based on a recent (December 8, 2020) USFWS memorandum that identified the use of a conservative value of $\lambda = 0.2$ for salmonids and alosine entrainment and $\lambda = 0.4$ for American eels. The TBSA analysis produced a range of survival estimates for turbine survival through the Project's E.L. Field powerhouse Kaplan units. Within that range of estimates, the probability of mortality due to blade strike increased as body size increased, a trend also identified in a review of the 1997 EPRI database by Winchell *et al.* (2000).

Estimates of total station survival for each target species/life stage were developed via empirical study (e.g., adult American eel, river herring, and American shad) or via a TBSA model informed with available empirical data and specific parameters associated with the E.L. Field turbine units. Estimates of total station survival were calculated at 75.5% for adult American eels, 80.1% for adult river herring, and 70.0% for adult American shad. A desktop based estimate of juvenile alosine total project survival was calculated at 94.8%. As with any estimate of total project survival, these values represent downstream passage success over the range of conditions during the evaluation. As noted in the revised Initial Study Reports which provided these estimates, river conditions during the passage periods were classified as normal to low flow. It is expected that as inflow conditions change the distribution of fish among available downstream passage routes will also change. These shifts in the proportional use among

passage routes has the potential to also shift the estimate of overall total project survival. The direction of that shift will be driven by the proportional use of passage routes with relatively higher or lower passage success rates for a particular species or life stage.

6 Variances from FERC-Approved Study Plan

The FERC-approved RSP indicated that Project turbines in the E.L. Field, Bridge Street, Hamilton and John Street powerhouses would be evaluated as part of the Fish Passage Survival Study. Since Boott has indicated that Final License Application for the Project (due to FERC by April 30, 2021) will exclude the Bridge Street, Hamilton and John Street stations as part of the Project in the future license, this effort focused on the two turbine units housed in the E.L. Field powerhouse on the mainstem Merrimack River.

The FERC-approved RSP proposed the use of a multiple-linear regression model for estimation of American eel turbine blade strike probabilities. This report substituted the newly available USFWS guidance for modification of the TBSA correlation factor (λ) from 0.2 to 0.4 to generate blade strike probabilities for American eels. In addition, turbine passage survival from the Downstream American Eel Passage Assessment was also included in this report and represents an empirical estimate of downstream passage survival for that species through the most frequently utilized passage route (i.e., the E.L. Field turbine units).

There were no additional variances from the FERC-approved study plan.

1 Introduction

Boott Hydropower, LLC (Boott) submitted their Revised Study Plan (RSP) to the Federal Energy Regulatory Commission (FERC) on January 28, 2019. Among the thirteen studies described in the RSP was the Instream Flow Habitat Assessment and Zone of Passage Study in the Bypassed Reach (the Study). FERC provided their Study Plan Determination (SPD) on March 13, 2019 and the Study was approved as filed. The purpose of this report is to describe study methodologies used to assess the flow:habitat relationship for target fish species and life stages in the Bypassed Reach (Bypass) and to evaluate the zone of passage assessment, and to detail the results of both Study components.

2 Objectives

As previously summarized in the RSP, there were two separate study elements requested to evaluate the bypassed reach, one pertaining to fish passage and one to aquatic habitat:

- Bypass Zone of Passage Assessment: determine flows which facilitate fish passage through the bypass reach through the use of detailed elevation and bathymetry data and two-dimensional (2D) modeling techniques;
- Instream Flow Habitat Assessment: determine impacts of a range of Project flows on wetted area and habitat for key aquatic species by conducting an instream flow study based on the Instream Flow Incremental Methodology (IFIM) process and one-dimensional (1D) modeling techniques.

These two study requests were subsequently combined into a single study. As detailed in the FERC-approved RSP, the Study was conducted via the application of a two-dimensional (2D) model of the bypassed reach to provide the results necessary to address both study elements and provide FERC with sufficient information to complete an environmental assessment.

3 Project Description and Study Area

The Lowell Project is located at River Mile (RM) 41 on the Merrimack River in the City of Lowell in Middlesex County, Massachusetts, with an impoundment extending approximately 23 miles upstream into Hillsborough County, New Hampshire. The existing Lowell Project consists of: (1) a 1,093-foot-long, 15-foot-high masonry gravity dam (Pawtucket dam) that includes a 982.5-foot-long spillway with a crest elevation of 87.2 feet National Geodetic Vertical Datum 1929 (NGVD 29) topped by 5-foot-high pneumatically-operated crest gates deployed in five independently-operable zones; (2) a 720-acre impoundment with a normal maximum water surface elevation of 92.2 feet NGVD 29; (3) a 5.5-mile-long canal system which includes several small dams and gatehouses; (4) a powerhouse (E.L. Field) which uses water from the Northern Canal and contains two turbine-generator units with a total installed capacity of 15.0 megawatts (MW); (5) a 440-foot-long tailrace channel; (6) four powerhouses (Assets, Bridge Street, Hamilton, and John Street) housed in nineteenth century mill buildings along the Northern and Pawtucket Canal System containing 15 turbine-generator units with a total installed capacity of approximately 5.1 MW; (7) a 4.5-mile long, 13.8-kilovolt transmission line

connecting the powerhouses to the regional distribution grid; (8) upstream and downstream fish passage facilities including a fish elevator and downstream fish bypass at the E.L. Field powerhouse, and a vertical-slot fish ladder at the Pawtucket dam; (9) appurtenant facilities; and (10) a 4,000 ft Bypassed Reach, which is the subject of this Study. The Project operates essentially in a run-of-river (ROR) mode using automatic pond level control, and has no usable storage capacity. As part of its relicensing proposal, Boott proposes to remove the four mill powerhouses and associated canal infrastructure from the Project's FERC license, retaining only the Pawtucket Dam, Northern Canal, E.L. Field Powerhouse and fish passage facilities. More detailed information is provided in Boott's application for new license.

The study areas for the zone of passage assessment and the aquatic habitat assessment were identical and both confined to the Bypass. The study area encompassed the length of the Bypass from just below the School Street Bridge (yellow line in Figure 3-1) downstream approximately 3,000 ft to the confluence of the Bypass and tailrace (green line in Figure 3-1). The 2D model for the zone of passage component was initially extended upstream from the bridge through the series of concrete passage weirs, however the model was not able to accurately describe velocity patterns associated with the artificial weir structures and consequently the passage assessment focused on the bedrock habitat below the bridge.

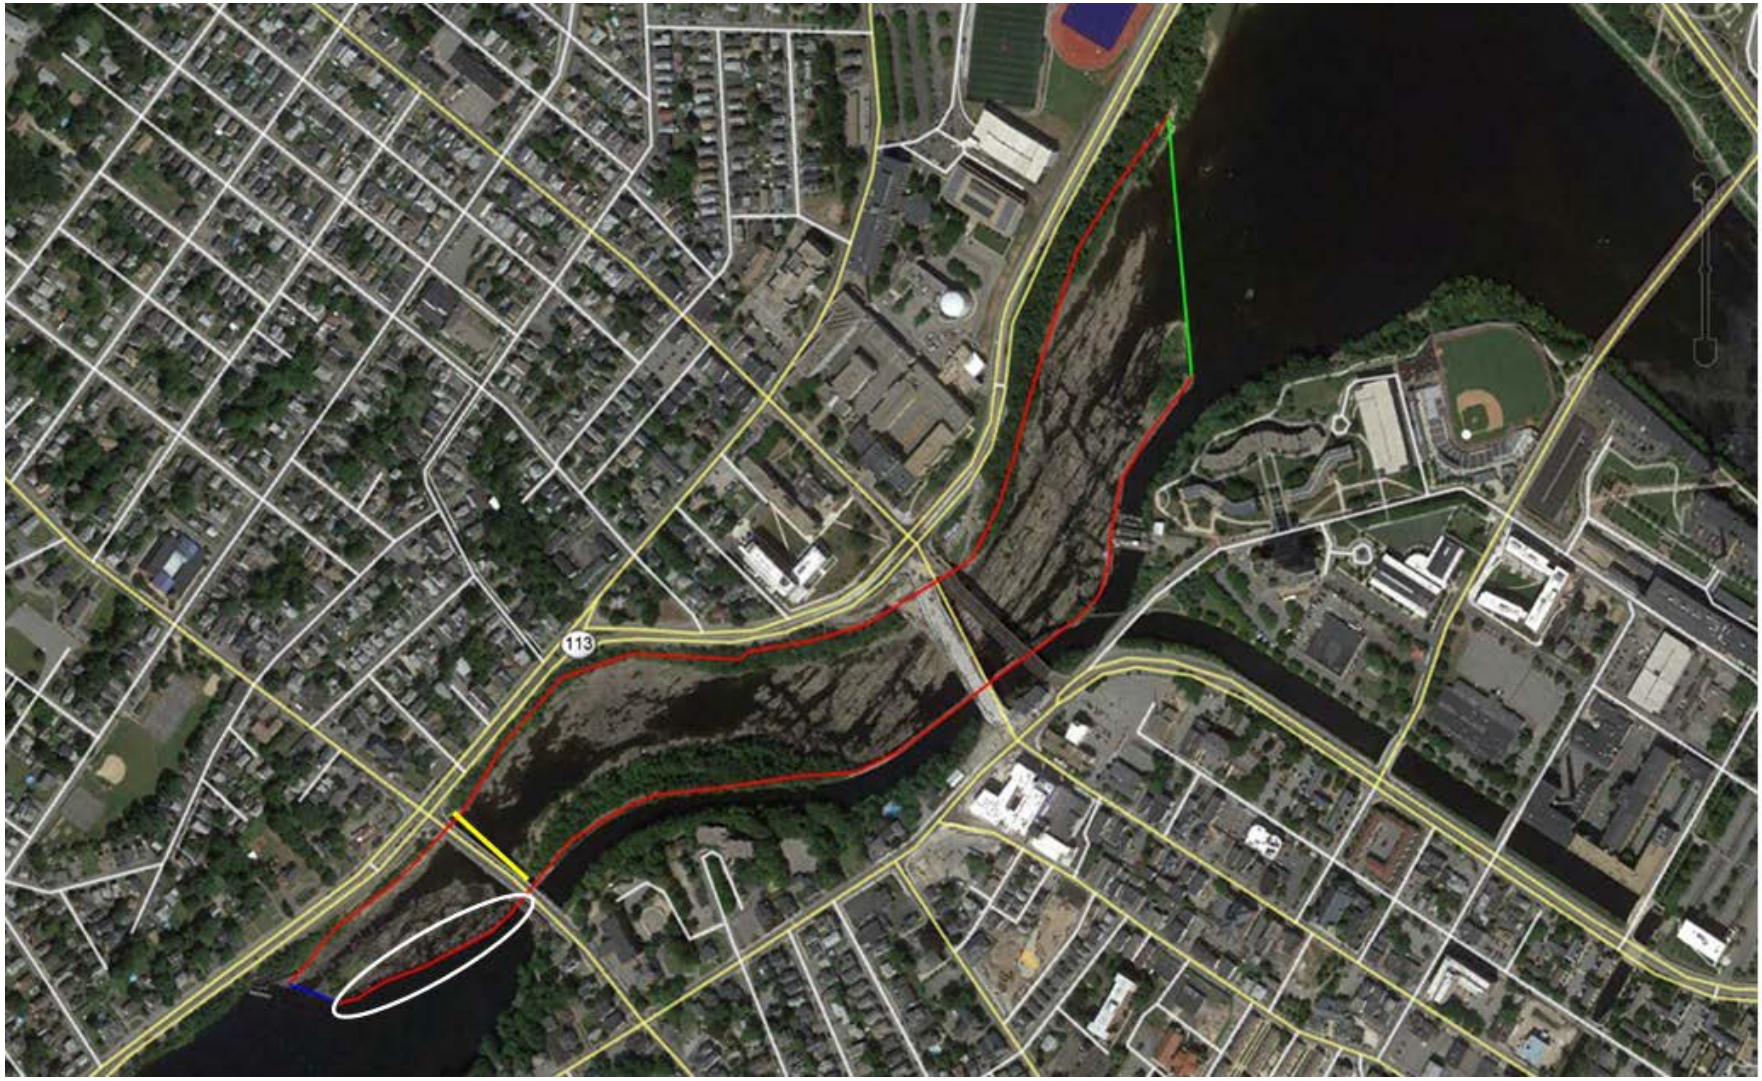

Figure 3–1. Spatial extent of the Bypassed Reach (red lines) showing the top boundary for both the zone of passage component and the aquatic habitat component (yellow line), the bottom boundary for both components (green line), and the parallel spillway (white oval) upstream of the modeled study reach.

4 Methods

4.1 2D Hydraulic Model

The 2D hydraulic model used to assess the zone of passage and aquatic habitat components of the instream flow study was River 2D (Steffler and Blackburn 2002), which is a depth-averaged model that incorporates Habitat Suitability Criteria (HSC) to evaluate the quantity and quality of aquatic habitat for selected species and life stages within the range of modeled flows. The River2D model uses a detailed topographic map of the study site to solve basic equations for conservation of mass and conservation of momentum in two horizontal directions to simulate water depths and velocities. Model inputs are bed topography, channel roughness, discharge at the upstream boundary, and water surface elevations at the downstream boundary. As noted in the River 2D manual "Obtaining an accurate representation of bed topography is likely the most critical, difficult, and time-consuming aspect of the 2D modeling exercise" (Steffler and Blackburn 2002). The topography for River 2D model is collected with higher density sampling in areas of more complex and/or rapidly varying habitat/bed features and lower densities in areas with more uniform topography (USFWS 2011). Some gaps in topography will occur in locations where depth, velocity, or other factors prevent safe data collection. The River 2D modules R2D_Bed and R2D_Mesh are used to generate bed topography and define the reach of interest using pointwise elevations and roughness.

Model calibration consists of adjusting the bed roughness values, if needed, in the model until a reasonable match is obtained between the simulated and measured water surface elevations. Water surface elevations predicted by the 2D model should be within 0.1 foot (0.031 m) of the water surface elevation measured at the upstream boundary (USFWS 2011). Once calibrated, the downstream water surface elevation and the inflow of the model are changed to simulate the flows of interest. Each flow change is run to a steady state solution. That is, for a constant inflow, the model is run until there is a constant outflow and the two flows are essentially equal. Typical convergence tolerance is within 1-5% of the inflow. Another measure of convergence is the solution change. Ideally, the solution change will become sufficiently small (0.00001) once converged. In some cases, the solution change will reach a relatively small value and not decrease any further, indicating a small, persistent oscillation at one or more points. This oscillation is often associated with a shallow node that alternates between wet and dry. This oscillation may be considered acceptable if the size of the variation is within the desired accuracy of the model (Steffler and Blackburn 2002). The ultimate goal is to define flow allocation through split channels and (in this case) accurately simulate fish migration pathways under low flow conditions.

The development of a 2D flow model requires the establishment of fixed boundaries at the upstream and downstream ends of the study reach. Those boundaries are required to be a single channel and be represented by a single water surface elevation (WSE) value for any given flow. The unique configuration of the spillway at the upstream end of the Bypass presents a challenge for establishment of the upstream boundary. The upstream fish ladder and associated attraction water system (AWS), as well as the 220 feet of pneumatic crest gate

closest to the northern bank (blue line in Figure 3-1) will discharge water in a linear fashion down through the full length of the Bypass. However, under conditions where flows are released from any of the pneumatic crest gate sections along the 765 feet of spillway oriented parallel to the Bypass channel (white oval in Figure 3-1), that discharge will not enter the uppermost section of the Bypass in a linear fashion. Spill-related inflows converging into the upper section of the Bypass would confound the 2D model if the upstream boundary is placed above that inflow.

As a result, the upstream boundary for the zone of passage and the aquatic habitat components of the Study was placed just below the School Street Bridge (yellow line in Figure 3-1). With the upstream boundary located at the Bridge, inflows provided from either the fish ladder and associated AWS system or any of the pneumatic crest gate sections are available at the model boundary in a more uniform (non-converging) flow pattern, and as a result permits modeling over a wide range of inflows to assess both passage and aquatic habitat.

4.1.1 Calibration Flows

A minimum of three calibration flows are required for collection of WSE and total flow (Q) at the upstream boundary, and WSE at the downstream boundary. The RSP recommended low flow calibration flow of 500 cfs, which represents the discharge from the fish ladder and associated AWS. The suggested high calibration flow target was ~7,800 cfs, which was the maximum combined discharge for the fish ladder, AWS system and 220 foot pneumatic crest gate, with a middle flow target of ~4,150 cfs (the midpoint between low and high flow targets). The general rule of thumb for instream flow evaluations is the ability to model downwards approximately 50% of the low flow, and upwards approximately 2 to 2½ times the highest calibration flow. Following that guidance, the calibration flows proposed as part of this study will theoretically support modeling from 250 cfs up to over 15,000 cfs. Actual measured calibration flows were similar to the proposed flows and ranged from 482 cfs for the low flow, 4,345 cfs for the middle flow, and 7,011 cfs for the high flow. As a result, modeled estimates could be generated over a range of flows from 250 cfs to 14,000 cfs.

4.2 Field Sampling

4.2.1 WSE and Flow Measurements

Collection of low, middle, and high calibration flow data occurred on 23 October 2019, 10 December 2020, and 4 December 2020, respectively. At each flow, WSE data were collected at several locations: just below the dam, at the fish ladder entrance, and just below the School Street Bridge (the upper boundary of the 2D model, Figure 3-1). WSE's were measured with a Real-time kinematic GPS (RTK) with a vertical accuracy of 0.1 ft. Total Bypass flow at low flow was measured at the downstream side of the School Street bridge using a Teledyne RDI Rio Grande 1200 KHz Acoustic Doppler Current Profiler (ADCP). The high flow and mid-flow discharge values were provided by the Licensee prior to each data collection event. Bypass flows were estimated by subtracting the flow reported at USGS gage no. 01099500 (Concord River below River Meadow Brook, at Lowell, MA) from USGS gage no. 01100000 (Merrimack River below Concord River at Lowell, MA), yielding inflow to the Pawtucket Dam, then

subtracting the calculated flow through the E.L. Field powerhouse turbines. Downtown canal flows were negligible during this period.

4.2.2 Bathymetry Measurements

As noted above, accurate bed elevation data is necessary to develop a 2D model that is representative of the actual study area. Stream bottom elevations within the Bypass were predominantly based on Light Detection and Ranging (LIDAR) data collected by Cornerstone Energy Services, Inc. on 24 October 2019 at a flow of 40 cfs. The estimated vertical and horizontal accuracy of the LIDAR output exceeded 0.1 ft. The LIDAR data was complemented by RTK measurements under riparian canopy and bridge structures where the LIDAR data was sparse or non-existent. RTK was also used to measure bathymetry in wadeable areas of the Bypass where LIDAR did not penetrate. This shallow water bathymetry data was collected during October 2019 under non-spill conditions within the Bypass. Bottom elevations in locations too deep to wade at low flow (i.e., depths >4 ft) were estimated using aerial photos, ADCP data, and RTK measurements. Substrate characterizations (see Section 4.2.3) were collected by two RTK crews at the same time.

4.2.3 Substrate Measurements

Bypass substrate was visually assessed on foot and via aerial photography in exposed bottom and shallow, wadeable areas using RTK to delineate polygons having specified substrate composition (Figure 4-1). Substrate was estimated in deeper, non-wadeable areas based on surrounding substrate characteristics and presence of eddy-forming features (e.g., bridge structures, point bars, etc.). Substrate composition was primarily used for assessing habitat suitability for each species and life-stage, according to their HSC (Section 4.4).

Polygons were defined by the percentage of dominant and subdominant substrate types in the following classes:

- Organics (ORG)
- Mud/Clay (MUD)
- Silt (SLT) (<0.003 inches)
- Sand (SND) (0.003-0.08 inches)
- Gravel (GRV) (0.08-2.5 inches)
- Cobble (COB) (2.5-10.1 inches)
- Boulder (BLD) (>10.1 inches)
- Bedrock (BED)

Where the substrate composition in a polygon was composed of two or more separate classes, the suitability of was calculated for each species and life-stage using the percentages of each type and the associated HSC values to calculate a weighted mean HSC value for that polygon. Crews noted that much of the gravel observed in the Bypass Reach was clean and laying on top of bedrock, suggesting it was very mobile and may not provide persistent habitat value.

4.3 2D Model Development

The RTK elevation data was combined with elevation data from the LIDAR to create the preliminary bed topography file. The resulting topography was edited in the River2D bed program by adding breaklines in order to refine the topography and interpolate between any gaps in coverage; resulting in the final digital elevation model used in the River2D program. In total, 692,252 survey points were used to create the topographic bed file (Figure 4-2), resulting in an overall point density of approximately 476 points/100 m^2. An artificial downstream extension was added to ensure a uniform outflow boundary and minimize any boundary effects in the model area of interest.

After finalizing the topographic bed file, a computational mesh was created for generating flow simulations. The final computational mesh had 18,223 nodes, 35,858 elements, and a mesh quality index of 0.38, which is within the River2D recommended quality index of 0.1 to 0.5 (Steffler and Blackburn 2002). Model calibration involved running the model at the three measured flows with a roughness value of 0.1. The modeled water surface elevations at the upstream end of the riffle were within 0.14 ft of the measured values (Table 4-1). After calibration, models were run to simulate flows from 250 cfs to 14,000 cfs. The downstream boundary conditions were set using a log-log rating curve created from the measured flows. A uniform Roughness (k_s) of 0.1 was used for all flow simulations

Model statistics for simulated flows are listed in Table 4-2. While solution change will ideally be below 0.00001 this is not always be achievable, especially at lower flows or in complex topography with many shallow depths. As noted in Steffler and Blackburn (2002):

> In some cases, the solution will reach a relatively small value of solution change (of the order of 0.03) and refuse to diminish further, regardless of the number of subsequent time steps. Usually, this indicates a small, persistent, oscillation at one (or sometimes more) points in the flow field. Often, the oscillation is associated with a shallow node that alternates between wet and dry. . . Finally, the oscillating solution may be considered acceptable, as the size of the variation may be within the desired accuracy of the simulation.

Given the high number of nodes in the model, the complexity of the topography, and the fact that the largest change was around our measurement accuracy, we found the results acceptable. In addition, the net Q was less than 1.1% in all of the model simulations, which is likely less than any error associated with flow measurements and the development of rating curves that were used to assign the upper and lower boundary conditions for the models, and the fact net Q was stable, we found the results to be acceptable. This rationale is consistent with findings in USFS (2011): "…we still considered these production cdg files for these sites to have a stable solution since the Net Q was not changing and the Net Q in all cases was less than 1.1%. In comparison, the accepted level of accuracy for USGS gages is generally 5%."

The bed elevations in wetted areas that were too dangerous or deep to collect topography with RTK were estimated using a combination of photos, aerial imagery, ADCP depth data and any nearby surveyed elevations.

4.4 Habitat Suitability Criteria (HSC)

HSC define the relative suitability of habitat variables for target species and life-stages, scaled from 0.0 (unsuitable habitat) to 1.0 (optimal habitat). HSC are the biological component of instream flow studies, and are directly incorporated into River2D for describing the flow:habitat relationship.

4.4.1 Target Species and Life-stages

Target fish species and life-stages were proposed for use in the RSP, then discussed and expanded upon during a May 21 2020 conference call with the relicensing participants. The species and associated life-stages used for the zone of passage component of this analysis are:

- American shad (adult passage)
- Blueback herring (adult passage)
- Alewife (adult passage)

HSC variables describing upstream passage criteria for each species were taken from USFWS (2019) and are presented in Table 4-3. The migratory species listed above (shad and river herring) are expected to require passage through the bypass reach to access upstream spawning habitat. Upstream passage criteria for American shad and river herring were generally taken from USFWS (2019) Fish Passage Engineering Design Criteria, which included maximum fish body depth, minimum weir opening depth, maximum weir opening velocity, and minimum weir opening width.

The species and associated life-stages used for the aquatic habitat component of this analysis are:

- American shad (juvenile, spawning)
- River herring (spawning)
- Smallmouth bass (fry, juvenile, adult, spawning)
- Fallfish (juvenile, adult)
- White sucker (fry, juvenile/adult, spawning)
- Longnose dace (juvenile, adult)
- Sea lamprey (spawning & incubation)
- Freshwater mussels (rearing)
- Benthic macroinvertebrates

The species and life stages listed above are those reasonably expected to utilize portions of the bypass for spawning and/or rearing. HSC variables describing aquatic habitat suitability for all species included mean column velocity, depth, and substrate are listed in Table 4-4, as well as the data sources associated with each HSC dataset. Graphical output of the HSC curves are presented in Appendix A.

Figure 4–1. Substrate polygon map of the Bypass Reach. See Section 4.2.3 for substrate code.

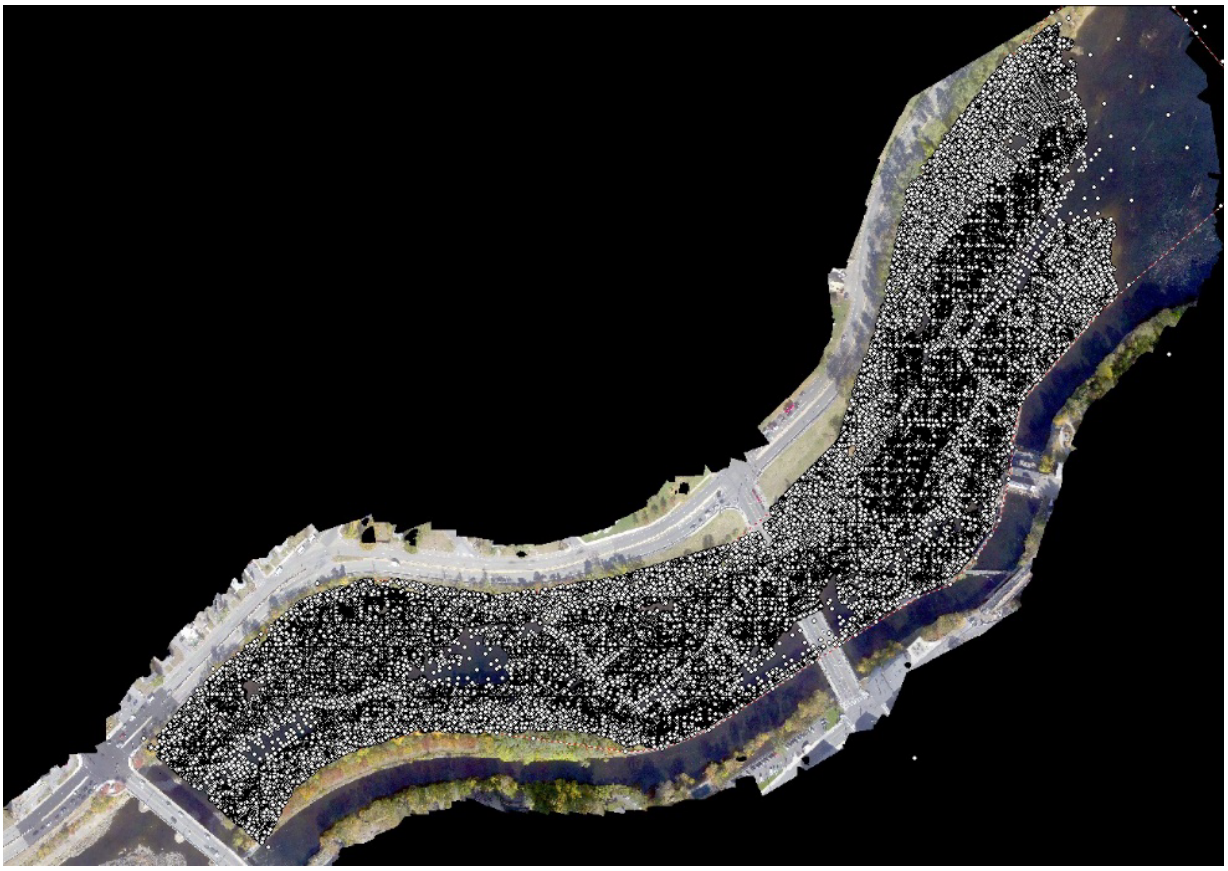

Figure 4–2. Topographic bed file for the 2D model (note-many nodes not visible in image).

Table 4–1. River2D calibration values.

Flow (cfs)	Measured stage (ft)	2D modeled stage (ft)	Difference (ft)
482	69.82	69.96	0.14
4,345	72.68	72.60	-0.08
7,011	73.74	73.62	-0.13

5 Results

5.1 Zone of Passage Assessment

The zone of passage model was developed for three migratory species (Table 4-3) in the Bypass Reach from the School Street Bridge downstream 3,000 ft through the bedrock rapids to the tailrace confluence. The minimum flow that provided a continuous and unbroken pathway (or nearly unbroken pathway) meeting the passage criteria was estimated by modeling passage opportunities at flows ranging from 250 cfs to 14,000 cfs. The passage assessment utilized values for minimum passage depth and maximum passage velocity. The passage analysis did not account for channel widths, which are routinely used in assessing passage through weirs and ladders; however given the large scale of the Bypass Reach and the complexity of the bedrock habitat, it is unlikely that channel widths would be limiting.

Assessment of the zone of passage was problematic due to the highly complex bedrock habitat throughout most of the Bypass Reach. It should be noted that the 2D model utilized actual measurements for developing the elevation model, except in areas that remained too deep and fast at low flow to safely measure (Figure 5-1), and consequently is expected to be relatively accurate in most locations. In contrast, all velocities were estimated via the hydraulic model, and in a highly complex habitat such as the Bypass Reach, in particular the lower bedrock-dominated channel, the model resolution for velocities may not be sufficiently accurate or precise to confidently assess passability in some areas. Also, the estimated velocities represent mean column velocities and do not account for near bottom velocities, which would be expected to be lower than mean column. Likewise, the velocity assessment is not expected to accurately represent zones of slower velocities along the margins of bedrock channels. For these reasons, the passage assessment largely utilized the reliable depth bathymetry in association with species passage depth criteria to identify connectivity of passage channels for shad and herring, with focused comparisons of velocity characteristics at specific pinch-points, such as the steep, bedrock cross-over channels.

5.1.1 American Shad

Complete, uninterrupted connection from the lower boundary to the upper boundary and the series of passage weirs, when both depth and velocity was considered, was never achieved for American Shad (see Appendix B for passage conditions at all modeled flows and for depth-only and velocity-only passage maps). Looking at the 2.5 ft depth criteria alone showed that near full connectivity did not occur until flows exceeded 4,000 cfs. The lack of passage habitat at low flows was largely due to the deep passage criteria for shad (Table 4-3), which at 2.5 ft was more than double the average body depth of adult upstream migrants. As flows increased above 4,000 the depths became more suitable for passage, but estimated velocities began to exceed the 8.25 fps passage criteria in many of the bedrock channels, which resulted in additional gaps in passable habitat.

Because the deep depth criteria may not be realistic for shad swimming through natural channels (as opposed to jumping weirs or ascending ladders), this analysis was re-run using the same 1.0 ft depth criteria used for river herring. Decreasing the minimum depth criteria from

2.5 ft to 1.0 ft for shad resulted in almost continuous passage opportunities at just under 500 cfs when using depth alone (Figure 5-2), with multiple continuous pathways becoming available at flows of 1,000 cfs and above (Appendix B). Zooming in on one of the most critical passage locations at 482 cfs (yellow box in Figure 5-2) shows that the gaps in depth passage are relatively short (~5m) and are likely not an impediment to passage for adult shad (Figure 5-3, top map). Almost the entire area shown in Figure 5-3 possesses velocities less than the 8.25 fps criteria for American shad (Figure 5-3, bottom map). Depth suitability for passage continues to increase at higher flows (Figure 5-4), and velocities largely remain suitable for shad until flows exceed 6,000 cfs (Appendix B).

5.1.1 River Herring

Passage conditions for river herring, using a 1.0 ft minimum depth criteria are the same as for the reduced depth assessment for American shad (Figure 5-4), and show almost continuous passage opportunities at 482 cfs with multiple continuous pathways becoming available at flows over 1,000 cfs (Appendix B). Because the herring velocity criteria is somewhat slower at 6.0 fps than for American shad, the 2D model predicted more impassable area within the bedrock channels due to rapid currents, however it appears likely that herring could ascend the channels along the bottom or along the margins at 482 cfs (Figure 5-5). Velocities within the bedrock habitat increase with increasing flows, with excessive velocities through the bedrock at flows over 4,000 cfs (Appendix B).

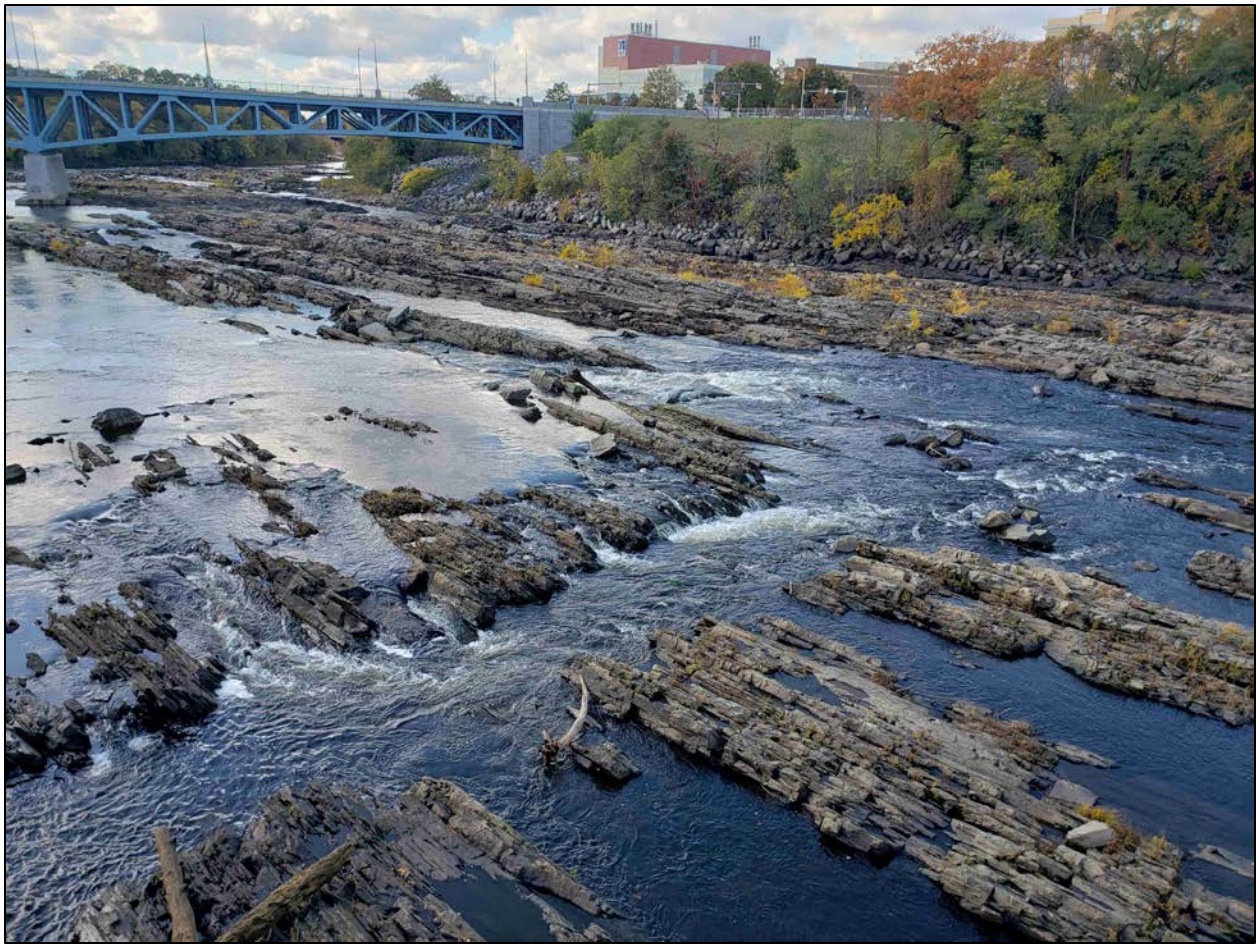

Figure 5-1. Complex deep and fast bedrock cross-over channels in the lower half of the Bypass Reach under low flow conditions. Image taken on Oct 23 2019 at a flow of approximately 480 cfs.

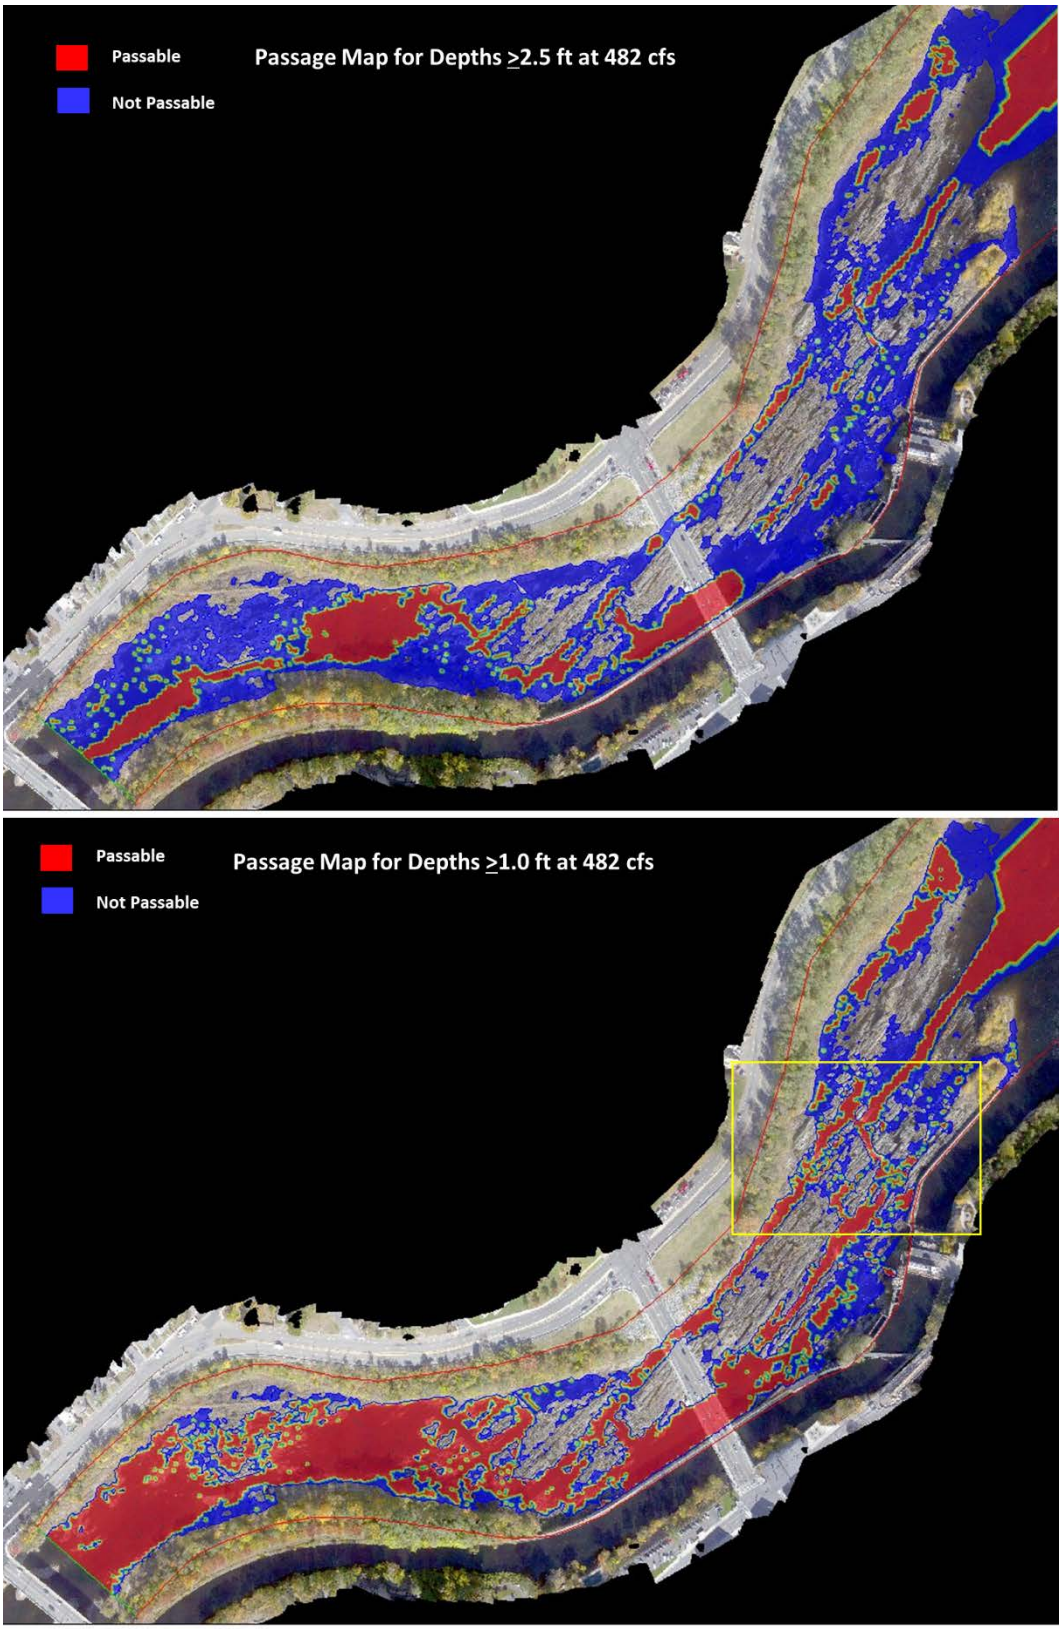

Figure 5-2. Comparative passage through Bypass Reach using minimum depth criteria of 2.5 ft (top map) and 1.0 ft (bottom map). Yellow box shows zoom area.

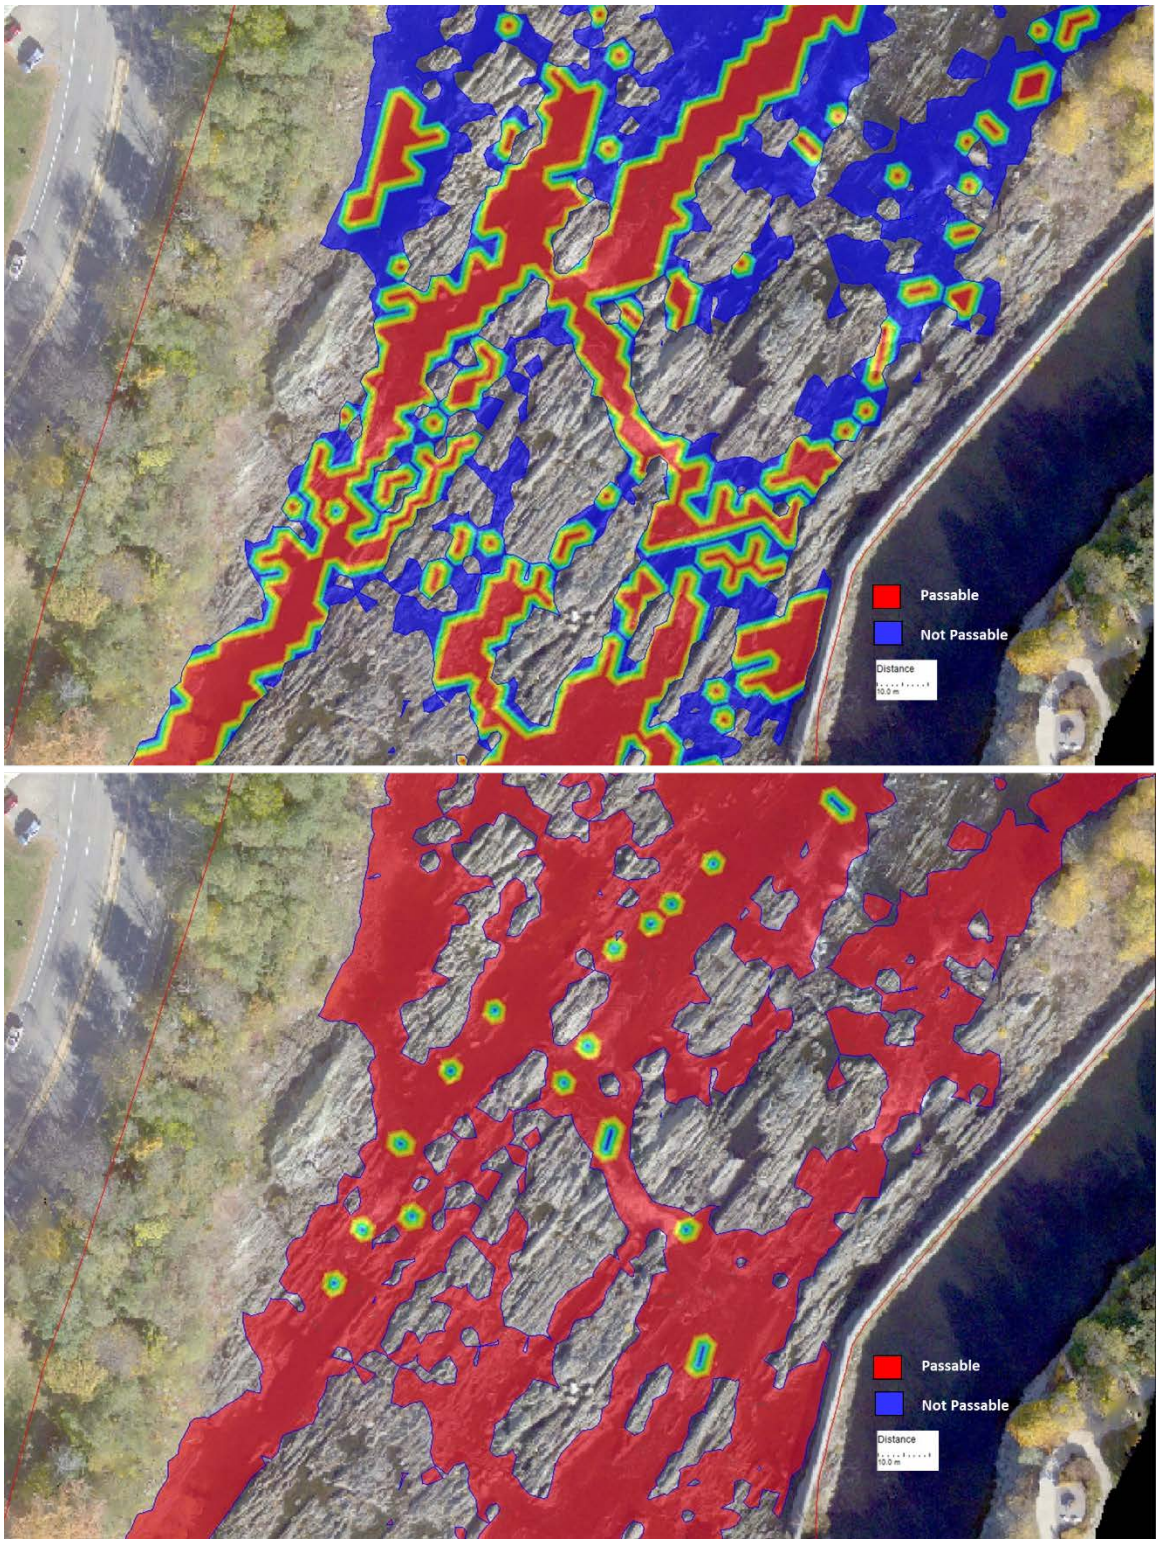

Figure 5-3. Close-up of bedrock cross-over channels in Bypass Reach showing 1 ft depth criteria (top map) and 8.25 fps velocity criteria (bottom map) for American shad at 483 cfs. (see Figure 5-1 for location of zoomed image).

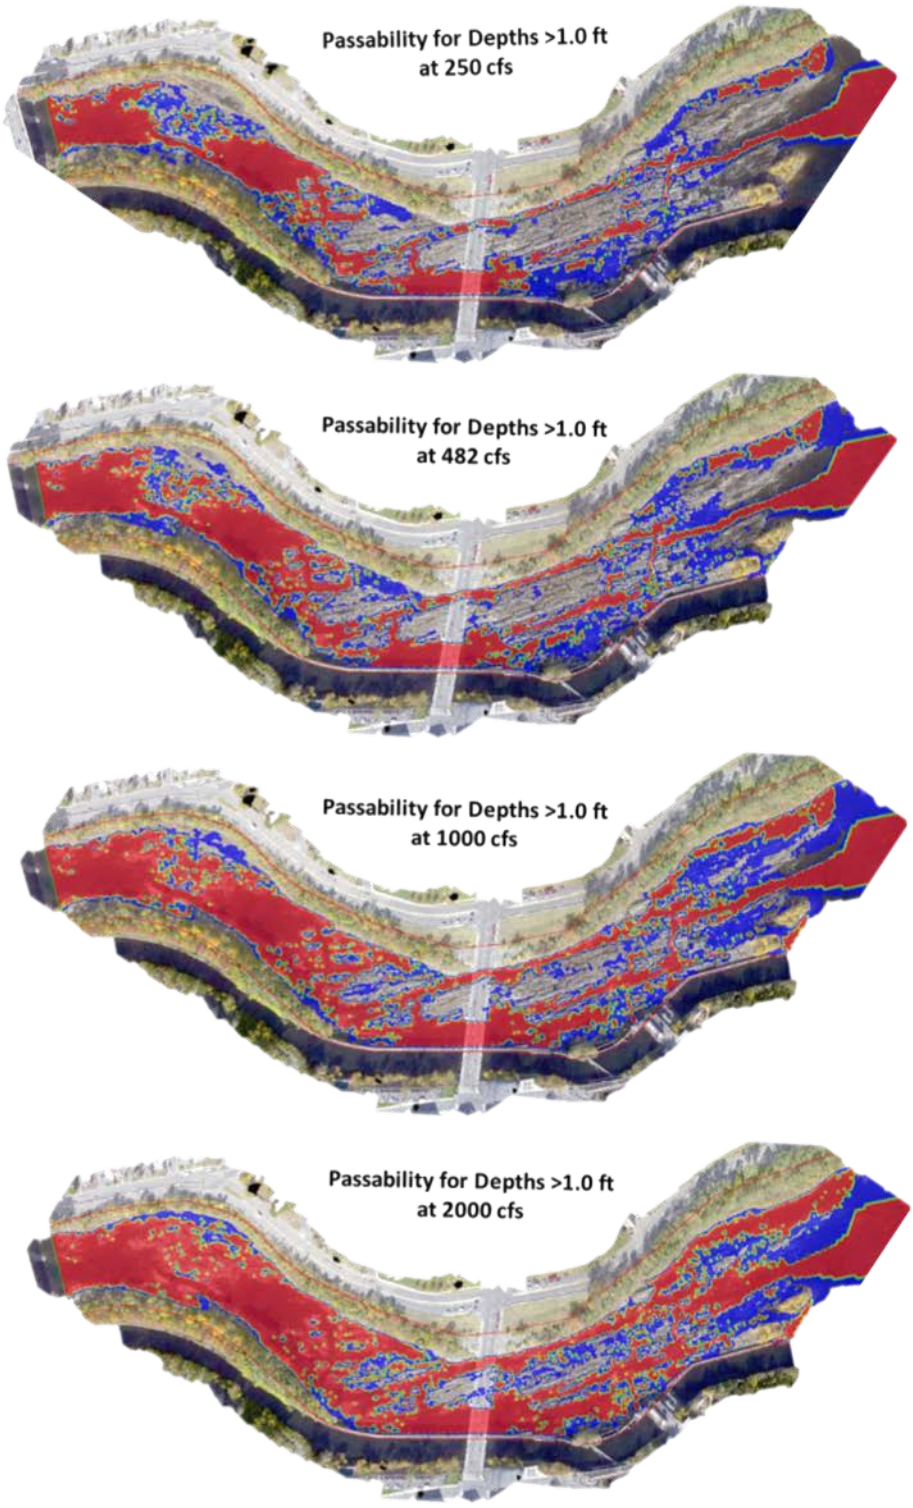

Figure 5-4. Comparative passage for American shad or river herring in the Bypass Reach for depths ≥1.0 ft at various flows. Red equal passable depth, blue non-passable.

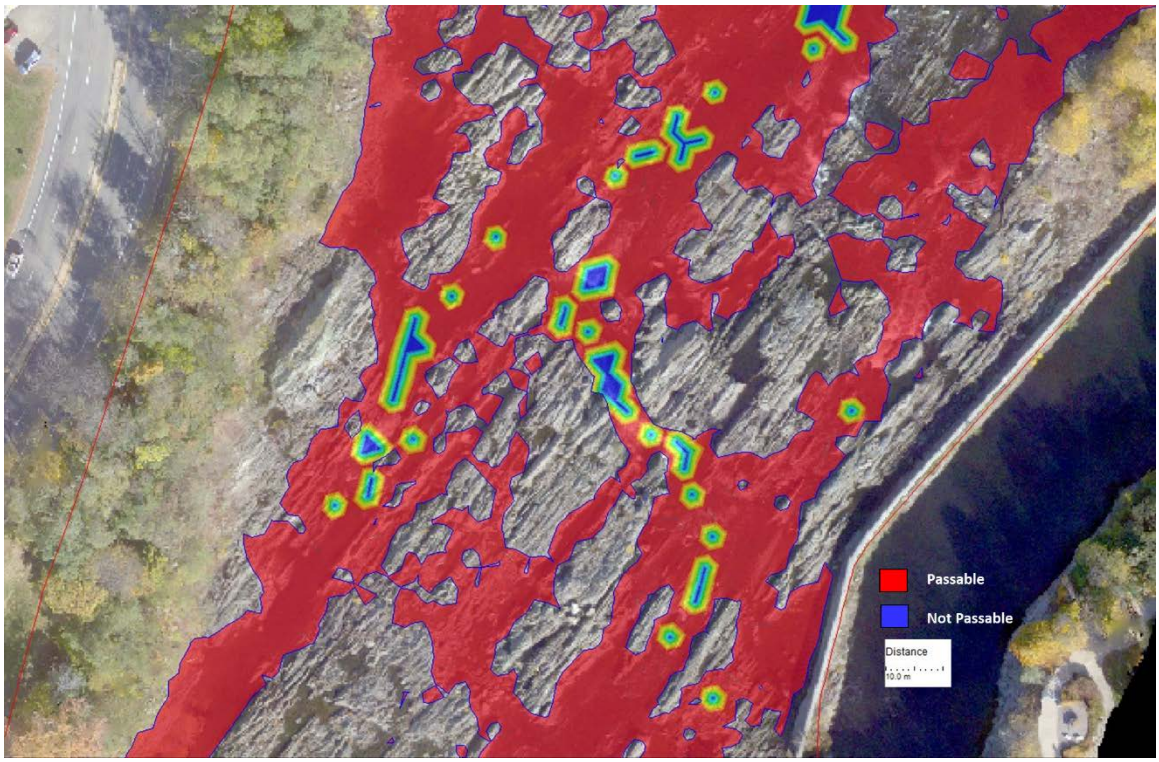

Figure 5-5. Close-up of bedrock cross-over channels in Bypass Reach showing 6.0 fps velocity criteria for river herring at 482 cfs. (see Figure 5-1 for location of zoomed image).

5.2 Aquatic Habitat Assessment

The aquatic habitat model was developed for 9 species and associated life stages in the Bypass Reach from the School Street Bridge downstream 3,000 ft through the bedrock rapids to the tailrace confluence at flows from 250 cfs to 14,000 cfs. An index of suitable habitat at each modeled flow, expressed as WUA in m^2, is presented in Table 5-1. Figure 5-6 illustrates the flow:habitat relationships for each species and life stage, and Figure 5-7 portrays the distribution and magnitude of WUA in the Bypass Reach for each species and life stage at the flow that provides maximum habitat.

5.2.1 American Shad

The index of suitable habitat (Table 5-1, Figure 5-6) for American shad juveniles remained relatively high (>10,000 m^2) at flows between 250 cfs and 2,000 cfs, with declining suitability to a minimum (3,641 m^2) at the maximum modeled flow of 14,000 cfs. The suitability index for shad spawning stayed high (>10,000 m^2) over a wider range of flows (1,000-8,000 cfs), with minima (~6,700 to ~5,700 m^2) at the lowest and the highest modeled flows, respectively. Most suitable habitat for both life stages occurred in the upper half of the modeled reach (Figure 5-7).

5.2.2 River Herring

The habitat index for spawning by river herring (Table 5-1, Figure 5-6) was highest at 3,110 m^2 at the lowest modeled flow (250 cfs), then progressively declined to 490 m^2 as flows increased to 14,000 cfs. Virtually all of the estimated habitat was of low suitability, due to the low suitability (0.1) for all rocky substrates (Table 4-4, Figure 5-7).

5.2.3 Sea Lamprey

Sea lamprey showed maximum habitat of 1,908 m^2 for spawning at 2,000 cfs flows (Table 5-1, Figure 5-6), with a declining habitat index to 355 m^2 at 14,000 cfs. Almost all of the suitable habitat occurred in the upper 1,000 ft of the modeled reach (Figure 5-7).

5.2.4 Fallfish

The habitat index for juvenile fallfish exceeded 1,000 m^2 at flows from 250 cfs to 2,000 cfs, with maximum habitat (3,134 m^2) at approximately 500 cfs (Table 5-1, Figure 5-6, Figure 5-7). Suitable habitat for adult fallfish was more available than for juveniles, with WUA estimates over 15,000 m^2 at flows from 250 cfs to 2,000 cfs, and a maximum of over 18,000 m^2 at 1,000 cfs. Juvenile habitat was largely restricted to the upper end of the modeled reach, whereas suitable habitat for adult fallfish was more widely distributed (Figure 5-7).

5.2.5 Longnose Dace

Suitable habitat for longnose dace juveniles was estimated at less than 1,000 m^2, except at about 500 cfs where WUA was 1,086 m^2 (Table 5-1, Figure 5-6). The habitat index for adult dace was somewhat higher, with WUA over 1,500 m^2 at flows from 250 cfs to 1,000 cfs, with a maximum of 2,414 m^2 at about 500 cfs. Most of the suitable habitat for both juvenile and adult

dace occurred in the upper end of the modeled reach above the area dominated by bedrock ledges (Figure 5-7).

5.2.6 Smallmouth Bass

The index of suitable habitat was highest for smallmouth bass fry (10,617 m^2) and spawning (879 m^2) at the lowest modeled flow of 250 cfs (Table 5-1, Figure 5-6), which is not unexpected due to the fry's weak swimming ability and the associated need for low velocities at bass nests. Suitable habitat for juvenile bass remained relatively high (>10,000 m2) at flows from 250 cfs to 2,000 cfs, with a maximum habitat index of 13,820 m^2 at 1,000 cfs. Adult smallmouth bass also showed maximum habitat (8,021 m^2) at 1,000 cfs, with a progressive decline to 2,016 m^2 at a flow of 14,000 cfs. Moderate to highly suitable habitat for fry, juvenile, and adult bass was distributed in both upper and lower ends of the modeled Bypass Reach, although spawning habitat was rare and confined to the upper region near the School Street Bridge (Figure 5-7).

5.2.7 White Sucker

The estimated WUA for white sucker fry, juvenile/adult, and spawning life stages all maximized at low flows (Table 5-1, Figure 5-6). The fry life stage showed high WUA at flows from 250 cfs to 2,000 cfs, with a maximum of 25,085 m^2 at the lowest modeled flow. Juvenile/adult WUA was 12,398 m^2 at about 500 cfs, whereas spawning WUA maximized at only 159 m^2 at 250 cfs. The low habitat index for sucker spawning was likely due to the HSC, which gave zero suitability for any substrate other than silt, sand, and gravel, each of which were rare in the Bypass Reach (Table 4-4, Figure 4-1). Both moderate and high quality habitat occurred for sucker fry and juvenile/adult life stages throughout most of the modeled reach, although habitat was spotty in the bedrock ledges (Figure 5-7). Suitable habitat for spawning was very rare and of low quality, due to the relative lack of suitable spawning substrate.

5.2.8 Freshwater Mussels

The 2D model estimated relatively high values of WUA for freshwater mussels, with indexes over 10,000 m^2 at 1,000 and 2,000 cfs, and a maximum of 11,066 m^2 at 2,000 cfs (Table 5-1, Figure 5-6). The abundance of suitable habitat is likely due to the broad preferences for coarse substrate types (Table 4-4), although most habitat was of low quality except in the area just downstream of the School Street Bridge and a small area adjacent to the powerhouse tailrace (Figure 5-7).

5.2.9 Benthic Macroinvertebrates

BMI showed the highest estimates of WUA of all species groups, with a maximum of 24,062 m^2 at 2,000 cfs, and maintained high habitat values (>10,000 m2) from 500 cfs to 10,000 cfs (Table 5-1, Figure 5-6). The high magnitude of WUA was largely due to the BMI's relatively high HSC value for bedrock at 0.5 (Table 4-4), which likely overestimates suitability of bedrock for EPT taxa (mayflies, stoneflies, and caddisflies), in comparison to Simulids and other midge species that have broader substrate preferences. The 2D model predicted suitable habitat for BMI throughout the Bypass Reach, although the highest quality habitat occurred in the upper end of the reach and near the bottom of the reach (Figure 5-7).

Table 5–1. Weighted Usable Area (WUA) in m^2 in the Bypass Reach according to flow, species, and life stage.

6 Summary

A two-dimensional (2D) hydraulic model was developed in the Bypass Reach extending from the School Street Bridge downstream approximately 3,000 ft to the confluence with the powerhouse tailrace. The 2D model was calibrated at low (482 cfs), middle (4,345 cfs), and high (7,011 cfs) flows, with simulated flows ranging from 250 cfs to 14,000 cfs. Lidar and RTK measurements were utilized to develop a digital elevation model of the Bypass Reach. Visual surveys were also conducted on foot to delineate polygons consisting of specified substrate characteristics. The 2D model was utilized to assess the relationship between Bypass Flow and upstream passage through the bedrock dominated reach by adult migrant American shad and river herring (blueback herring, and alewife). The 2D model also assessed the relationship between Bypass flows and the quantity and quality of aquatic habitat, expressed as Weighted Usable Area (WUA), for 9 species groups and their associated life stages.

6.1 Summary of Zone of Passage Results

Assessment of the zone of passage was challenging due to the highly complex bedrock habitat throughout most of the Bypass Reach. Complete, uninterrupted connection from the lower boundary to the upper boundary at the School Street bridge, when utilizing passage criteria for both depth and velocity, was never achieved for either American shad or river herring. The 2D model identified numerous potential gaps in suitable passage habitat in the lower half of the Bypass Reach downstream of the University Avenue Bridge. From review of the zone of passage model imagery alone it is unclear if these gaps would be absolute barriers to upstream migration or if passage would be possible along the margins of the impassable gaps. Given the uncertainty in the modeled depth-averaged velocities through the lower, complex bedrock area, the passage analysis focused on flows meeting the depth criteria, with closer inspection of modeled velocities at identified pinch-points (e.g., narrow/fast bedrock channels).

In addition, the shad assessment was reanalyzed using a more realistic minimum depth of 1.0 ft (same as herring), which provided a near-continuous passage channel at flows of approximately 500 cfs, with multiple passage channels at higher flows (Figure 5-4). Passage opportunities based on depth alone increased with flows, but velocities became limiting at flows over 6,000 cfs (Appendix B). Likewise for river herring, depths became suitable for passage by 500 cfs, with excessive velocities through bedrock channels at flows of 4,000 cfs and greater. Note that these assessments do not account for channel widths, however given the large scale of the Bypass Reach and the complexity of the bedrock habitat, it is unlikely that channel widths would be limiting.

As part of the *Upstream and Downstream Adult Alosine Passage Assessment* study, movements of radio-tagged adult river herring and American shad were monitored within the Bypass Reach during spring 2020. As described in that technical report, flows through the Lowell Bypass Reach during the 2020 monitoring period were comprised of the ~500 cfs of water constituting the attraction and conveyance flow associated with the Pawtucket Dam fish ladder as well as incidental spill flow passing over the spillway. Incidental spill flows in excess of 500 cfs were present until May 21 after which incidental spill was reduced to near zero through the month of

June (Figure 6-1). A total of 105 unique foray events for radio-tagged adult river herring into the Bypass Reach were recorded during the 2020 study. These events were recorded over a range of dates from May 7 through May 23 with the majority of events occurring between May 17 and 19. When the average Bypass Reach discharge condition occurring during each upstream foray is considered, foray events resulting in successful passage at the Pawtucket Dam fish ladder occurred over a range of Bypass Reach flows from 883 to 4,432 cfs. Conversely, foray events which did not result in successful upstream passage and were determined to have ended at or near to the midpoint of the Bypass Reach occurred over a range of flows from 907-2,145 cfs and those that ended at the upstream end of the Bypass Reach occurred over a range of flows from 799 to 2,587 cfs. The probability of successful upstream passage for radio-tagged adult herring was evaluated using a Cormack Jolly-Seber model for the lower and upper portions of the Bypass Beach and was estimated at 72% and 92%, respectively. Although tagged adult herring were only detected through May 23 within the Lowell Bypass Reach, camera operations at the Pawtucket Dam fish ladder continued to document migrating river herring through the first week of June. Mean daily discharge values for flow through the Lowell Bypass Reach between May 24 and June 6 ranged from 900 to 546 cfs. A net total of 42,066 adult herring passed during that period (Figure 6-2)

Movements of radio-tagged adult American shad during the 2020 passage evaluation were limited to a single detection at the lowermost receiver station. When considered with findings from this zone of passage assessment it appears that shad have difficulty migrating upstream through the Bypass Reach. However, camera operations at the viewing window of the Pawtucket Dam fish ladder documented the upstream passage of 799 adult American shad over a range of dates from May 18 to June 26 with the majority of passage events documented during early and mid-June (Figure 6-3). Reported Merrimack River inflow during the period of peak shad detection in the Pawtucket Dam counting window during 2020 was below the E.L. Field Powerhouse capacity of 8,000 cfs; consequently no spill occurred over this period (Figure 6-1) and discharge through the Bypass Reach was limited to ~500 cfs from the Pawtucket Dam fish ladder (Figure 6-3).

Despite poor performance of tagged shad and the lack of passage connectivity through the Bypass Reach according to the 2D model (using the 2.5 ft minimum depth criteria), a proportion of adult shad were able to reach the Pawtucket Dam fish ladder under a Bypass flow of about 500 cfs. This is consistent with the revised 2D model using a 1.0 ft minimum depth criteria for shad, which suggested near continuous passage opportunities at a flow of approximately 500 cfs.

6.2 Summary of WUA Results

In most cases the habitat indexes for each species and life stage showed maximum suitable habitat at relatively low flows through the Bypass Reach (Table 5-1, Figure 5-6). Thirteen of the 17 assessments produced maximum WUA at flows of 1,000 cfs or less, with 3 other species/life stages (lamprey spawning, freshwater mussels, and BMI rearing) reaching maximum WUA at 2,000 cfs, and one species/life stage (shad spawning) showing maximum habitat at a higher flow (4,345 cfs). This result is primarily due to the steep, bedrock dominated habitat that characterizes the Bypass Reach. In terms of the magnitude of suitable habitat, the habitat index showed highest values for shad, adult fallfish, sucker fry, and BMI, each with maximum WUA estimates exceeding 15,000 m^2. In contrast, relatively little suitable habitat was predicted for lamprey spawning, bass spawning, sucker spawning, and juvenile longnose dace; all of which had maximum WUA values of less than 2,000 m^2. WUA distribution maps (Figure 5-7) revealed that most suitable habitat occurred in the upper 1,000 ft of the modeled reach, with limited suitable habitat in the lower, bedrock-dominated area.

7 Variances from FERC-Approved Study Plan

As previously noted, the 2D model for the zone of passage task was initially intended to encompass the series of weirs located in the upper end of the Bypass Reach upstream of the School Street Bridge. However the model was unable to run to a steady state solution due to unrealistically high velocities (greater than 2,000 fps) at nodes along the vertical edges of the weirs, which caused the time step to drop to infinitesimally small levels, and preventing the model from advancing beyond a few seconds. Consequently, the upstream boundary for both the zone of passage and the aquatic habitat elements of this study was placed just downstream of the School Street Bridge to avoid the transverse flow coming from the diagonal spillway.

The FERC-approved RSP notes that NMFS requested ADCP velocity data at randomly placed cross sections under the high calibration flow collection. Although not necessary for 2D model development, such data can be useful as validation data. However, we could not physically access locations for collecting validation data during the high flow event, and the current velocities in many areas was determined to be too fast and would exceed the capabilities of the ADCP trimaran. Consequently, transect validation data was not performed.

Due to the complexity of the bedrock-dominated habitat, both "minimum" and "optimal" passage flows were not identified. Instead, the minimum flow meeting passage depth criteria was identified for American shad and river herring, along with the range of potential passage flows based on both depth and velocity criteria.

There were no additional variances from the FERC-approved study plan in this task.

1.0 INTRODUCTION

Boott Hydropower, LLC (Boott) is the licensee, owner, and operator of the 20.2-megawatt Lowell Hydroelectric Project (Project or Lowell Project) (FERC No. 2790). Boott operates and maintains the Project under a license from the Federal Energy Regulatory Commission (FERC or Commission). The Project's existing license expires April 30, 2023. Boott is pursuing a new license for the Project using the Commission's Integrated Licensing Process (ILP), as defined in 18 Code of Federal Regulations (C.F.R.) Part 5. In accordance with 18 C.F.R. § 5.15, Boott has initiated the Historically Significant Waterpower Equipment Study as provided in the study plan and schedule approved in the Commission's March 13, 2019, Study Plan Determination (SPD) for the Project. This report presents the results of the Historically Significant Waterpower Equipment Study.

The Study Report's stated goals were to:

- Consult with the National Park Service (NPS) and conduct a site visit to identify historically significant waterpower equipment of interest to the NPS for potential future interpretation, exhibition, or as scrap equipment to maintain and operate other historic machinery;
- Photodocument historically significant waterpower equipment identified in consultation with the NPS;
- Conduct background research on the history of identified waterpower equipment, including designer/engineer, dates of manufacture and use, and an explanation of how the equipment was or is used;
- Document current ownership of historically significant waterpower equipment; and
- Prepare a report summarizing the results of the Historically Significant Waterpower Equipment Study.

2.0 HISTORIC BACKGROUND

The City of Lowell is considered the birthplace of large-scale manufacturing in the United States. Lowell's success depended upon a variety of factors, but one of the most significant was the efficient use of the Merrimack River's waterpower. Begun as a transportation canal, the Lowell Canal System evolved during the nineteenth century into one of the nation's most important waterpower sites.

The Merrimack River originates south of Franklin, New Hampshire, where the Pemigewasset and the Winnepesaukee rivers join. From this point, the Merrimack flows 110 miles, and drops 269 vertical feet, to its mouth in Newburyport, Massachusetts. One of the principal vertical drops along this route occurs at Pawtucket Falls, just south of the New Hampshire state line in Lowell. Here the free-flowing Merrimack dropped more than thirty feet over a series of rapids. Below Pawtucket Falls, the Merrimack swings sharply to the southeast where, after a mile or so, the Concord River flows into the mainstream from the south. The river then swings back to the northeast and continues roughly thirty-seven miles to the sea.[1]

In 1792, a group of Newburyport merchants formed a company to build a canal around Pawtucket Falls. Circumventing the falls was expected to increase the flow of forest products from New Hampshire to Newburyport. The Proprietors of the Locks and Canals on Merrimack River (PLC), as the enterprise was styled, began construction in fall 1792. Work progressed in fits and starts, with the canal opening to traffic in fall 1796.[2]

The canal had to be deepened and its locks rebuilt or repaired several times during its first decade of operation. By 1821, the canal, then known as the Pawtucket Canal, included three single locks, the Guard Locks, Minx Locks, and Swamp or Upper Locks, and a flight of three locks in a row, known as the Lower Locks.

In 1821, the Boston Manufacturing Company (BMC), founded in 1813 by Francis Cabot Lowell, a Boston merchant, was seeking a location for new cotton mills. The BMC operated a fully integrated cotton mill in Waltham, Massachusetts, the first such mill in the world. Raw cotton entered the mill and, because of mechanical operations driven by waterpower, emerged as cloth. In 1821, the firm sought a new location for the production and printing of calicoes, a form of cloth not then produced in the United States. The firm sought land and adequate waterpower for factories, print works, and corporate housing, and began secretly purchasing the stock of the PLC, as well as land near the Pawtucket Canal. By 1822, the new venture had acquired control of the PLC, had formed itself as the Merrimack Manufacturing Company, and was ready to enlarge the Pawtucket Canal, erect its first mill, and construct a branch canal to the mill site.[3]

The purpose of every modification to the canal system was to provide a dependable and predictable flow of water to each mill site. Initially, this involved securing a reliable flow through Pawtucket Canal. The gates of the canal's locks opened and closed, admitting and releasing water into the system in accordance with the needs of traffic on the canal. This method of operation failed to provide the predictable flow of water required by the mills, so one of the first major building campaigns entailed construction of dams at each of the canal locks. Between 1822 and 1824, the Merrimack

[1] J.W. Meader, *The Merrimack River: Its Source and Its Tributaries* (Boston, MA: B.B. Russell, 1869).
[2] Patrick M. Malone. *Waterpower in Lowell: Engineering and Industry in Nineteenth-Century America* (Baltimore, MD: Johns Hopkins University Press, 2009), 12.
[3] Ibid., 22–24.

Manufacturing Company rebuilt the Pawtucket Canal to enable it to serve as both a power and transportation canal. The locks at the Guard Locks, Swamp Locks, and Lower Locks were rebuilt in stone, lined with wood. New dams, fitted with sluice gates, were constructed at each location. These dams created pools of water that could be used to provide water to the downstream mills, regardless of whether the canal locks were open or closed.[4]

Over a period of about twenty-five years, following the Merrimack Manufacturing Company's acquisition of control of the PLC in 1822, the transportation canal constructed around Pawtucket Falls was expanded and enlarged in a series of major building campaigns (Figure 2-1). By 1823, the newly constructed dam at Swamp Locks provided water for the Merrimack Canal. By 1826, the Lowell Canal branched off the Merrimack Canal and provided power for the Lowell Mills, while the Hamilton Canal branched off the Pawtucket Canal above Swamp Locks and provided power to the Appleton and Hamilton mills. In 1831, the Western Canal also branched off the Pawtucket Canal and served the Suffolk, Lawrence, and Tremont mills. In 1836, the Eastern Canal branched off the lower Pawtucket Canal and powered the Boott Mills. By 1836, the first stage of canal construction was complete. It constituted a two-level system, with the Western, Merrimack, Lowell, and Hamilton canals, all of which took their water from above Swamp Lock Dam, comprising the upper portion of the system, and the Lower Pawtucket and Eastern canals, fed from below Swamp Locks Dam, comprising the lower portions. The second great phase of construction was completed by 1848. Beginning in 1846, the construction of the Northern Canal and the Pawtucket Gatehouse brought water directly from the Merrimack River to the lower reaches of the Western Canal, reversed the flow of water in the upper reaches of the Western Canal, and, by means of the Moody Street Feeder, brought water to the lower stretch of the Merrimack Canal.[5]

This complex system of canals delivered the waterpower of the Merrimack River to the mills of ten textile corporations. Beside the lower Pawtucket Canal, stood the mills of the Hamilton, Appleton, Lowell, and Merrimack corporations, as well as the massive machine shop of the PLC. The Massachusetts and Boott mills stood between the Eastern Canal and the Merrimack River, while upstream were the Merrimack mills and the printworks and factories of the Lawrence Corporation. The Tremont and Suffolk mills flanked the Western Canal. This network of canals "formed a dynamic system which was only in equilibrium when proper water levels were maintained."[6] The engineering plan called for water to generate power on both levels of the system, to enter the lower canals only after passing through the wheel pit of an upper-level mill. This required upper-level water users to discharge at least as much water as the lower mills required.

Reduced discharge from upper-level mills could be offset by allowing supplemental water to flow directly from the upper to the lower levels. On the Western Canal, this could be done at the Hickey Hall Dam, while the flow in the Pawtucket Canal could be augmented by releasing water at Swamp Locks Dam. Managing the flow of water through this complex system required careful coordination. A system of dams and gatehouses helped control the flow of water and was intended to assure that all users were adequately supplied with power.

3.0 STATUS AND SIGNIFICANCE

The Lowell Locks and Canals Historic District was listed in the National Register of Historic Places (NRHP) in 1976. The nomination's statement of significance reflects the standards of the time, and states that the district is significant "for its contributions to the development of Lowell as the first great industrial city in the United States." The statement of significance acknowledges the complex engineering involved in the construction of the canals and notes that "each new canal was built in an attempt to solve the problem of keeping all the mills supplied with a sufficient supply of power."[7] The established period of significance for the district is 1790–1870, though this periodization privileges the period when waterpower was used to directly drive mill machinery through the use of shafting and belting, and does not encompass the entire period of significance for the locks and canal system and its component resources.

The significance of the Lowell canal system is inherently bound up in the fact that it is a system whose successful operation is dependent upon all its individual component elements. No individual component element is more significant than any other since the successful functioning of the system relies upon all the components. Certainly, a particular canal, or a particular mill, could function without some elements of the system, but the system, as a whole, depended upon all its component elements. The resource is the system, not the system's individual elements.

After the initial design and construction of this system, lay a continuing series of engineering and management challenges to maintain and operate the system and, over time, to expand the system to meet growing demand. These challenges included meeting the at times conflicting requirements of power users, devising methods and equipment for measuring and monitoring the use of water, discouraging the waste of water, and, in periods of seasonal shortage or drought, rationing the use of the available water. Increasing the efficiency of the system by eliminating waste and improving the efficiency of every system component became imperative. This imperative applied to the penstocks, gates, and waterwheels of the mills, as well as to the dams and canals that supplied the water to the mills.[8]

The daily operation of this complex waterpower system, with multiple canals, dams, gate houses, and lesser elements, placed an enormous strain on the various system components. Floods, freshets, and other natural events compounded the wear and tear associated with daily operation. Many of the gates, sluices, and other elements that controlled the flow of water originally were constructed of wood and, therefore, subject to rot, and in need of regular maintenance, repair, and replacement. In addition to the daily wear and tear on system components, changes in the operations at individual mills could change demands for water, necessitating modifications to the system to meet this demand.[9]

These and other factors meant that since the initial construction of the Lowell Canal system nearly 200 years ago, the various component parts of the system have been subject to almost continuous repair, alteration, replacement, or improvement. In this environment of continual change, it follows that changes may be made to components of the system without adversely affecting the qualities and characteristics that make the system itself eligible for the NRHP.

4.0 CONSULTATION WITH NPS

In consultation with the NPS, Boott clarified the goals of this study during the December 18, 2019, Study Workshop held at the Lowell National Historical Park Visitor Center. The main goal of the study, as provided for in the approved study plan, was the identification of historically significant waterpower equipment "of interest to the NPS." However, Boott understands NPS's goals for this study include the determination of what original hydroelectric equipment is owned/operated by Boott within the Project Boundary is historically significant on a national level, not necessarily simply "of interest to the NPS." In other words, the selection of equipment to include in the analysis should not be limited to NPS' explicitly stated interest.

In July 2020, a site visit was held at Lowell to visit various locations associated with the control of water through the canal system. This tour included inspection of the Swamp Locks Gate House, the Hamilton Wasteway Gate House, the Lower Locks Gate House, the Boott Dam Gate House, the Moody Street Feeder Gate House, and the Northern Canal Gate House. Various types of gate operating mechanisms were observed. Discussions with NPS personnel indicated that they viewed the gate houses and their mechanisms as part of a larger system, as outlined above.

The majority of the gate operating equipment consisted of a rack-and-pinion system, originally operated by hand, but subsequently converted to electrical operation. The Boott Dam Gate House featured a hydraulic operating system, while the Northern Canal Gate House retained its original belt-driven line shafting, originally powered by the first Francis turbine installed in the United States.

5.0 HISTORICAL BACKGROUND OF OPERATING SYSTEM COMPONENTS

Gray & Pape conducted documentary research in the records held by the NPS at Lowell to identify the component elements of the larger canal system and the equipment used to operate water control devices throughout the system. The research effort also focused on developing a chronology of the alterations to individual components of the system. The results of the research effort are presented below (organized by canal) and progressing from upstream to downstream.

5.1 Pawtucket Canal - Guard Locks[10]

Between 1822 and 1823, Kirk Boott oversaw the reconstruction of the Guard Locks. Boott had a new channel cut around the existing locks and built a guard dam, with sluice gates, in this channel to regulate the flow of water downstream. In 1832, the dam was removed and rebuilt approximately 23 feet further downstream. At this date, the dam had five sluice gates sheltered in a wooden gate house. Subsequent modifications include:

- 1848 dam raised in height;
- 1856 sluice gates replaced;
- 1869 Francis-designed rack-and-pinon system for operating gates;
- 1870 Francis-designed hydraulic gate hoist system that employed five water-powered metal cylinders, each measuring 27 inches in diameter and 10 feet tall (cylinders, pistons, and rods manufactured by IP Morris & Company, rest of hoisting apparatus by Lowell Machine Shops[11]);
- 1870 existing brick gate house constructed;
- 1902 headgate sluices enlarged and extended;
- 1965 three middle hydraulic operating cylinders replaced, with oil hydraulic cylinders and pistons.

5.2 Pawtucket Canal - Swamp Locks[12]

Between 1822 and 1823, a 13-foot-tall stone dam, with sluice gates, was built adjacent to the Swamp Locks. The dam was rebuilt in a stepped configuration in 1841, at which time it is likely that the deep gate and sluiceway were added in the south portion of the dam. The dam underwent extensive repairs in 1850, and a gatehouse was constructed at about that time. Later alterations include:

- 1918 dam raised 1 foot in height;
- 1922 installed 2 additional 8-foot square waste gates and a small hydroelectric station to carry the Locks & Canal Yard light and power load; installation of waste gates required removal of 4 feet from top of dam for 20 feet[13];
- 1927–1928 sluice gate constructed between dam and locks, with gate house,

[13] Proprietors of Locks and Canals Records, 1813–1962. Series II. General Files. Box 50, Folder 1 – Swamp Locks, 1897–1952. On file at Lowell National Historic Park.

- 1952 deep gate operation motorized with 3/4hp gear head motor, with sprockets and chain;
- 1953 gates converted to operate by remote control;
- 1971 north segment of gate house, covering 11 bays, removed.

5.3 Lower Pawtucket Canal - Lower Locks[14]

The Lower Locks were rebuilt in 1823, with a new dam constructed north of the locks. About 1841, a sluiceway was constructed at the north end of the dam. This was reconstructed and fitted with waste gates in 1887. Between 1946 and 1958, three concrete spillways were constructed over the dam.

5.4 Merrimack Canal[15]

In 1918, Locks and Canals proposed constructing a gate structure at Merrimack Dam. The Holyoke Machine Company of Worcester, Massachusetts, provided information for a hand-operated hoist system to be used for operation of a 3- by-8-foot gate. In October 1918, the work was delayed.

- Merrimack Canal Guard Gates
- YMCA Gates
- Moody Street Feeder Gate House
- Boott Penstock
- Merrimack Wasteway

5.5 Hamilton Canal - Wasteway Gate House

The two gates located in this building are operated by a rack-and-pinion system, with granite counterweights (Figure 5-1). The hoisting apparatus dates from 1903 and is similar in design and appearance to extant rack-and-pinion mechanisms in other locations, such as Swamp Locks and Lower Locks, within the system. This suggests that these rack-and-pinion mechanisms may all date from ca. 1900 (Figure 5-2).

5.6 Western Canal - Tremont Gates[16]

A 1911 blueprint shows a proposed arrangement for hoisting the gates by electric motor. In 1937, control of these gates was managed remotely from Lawrence Dam.

5.7 Western Canal - Lawrence Dam, Waterway & Canal[17]

In 1918, modifications were made to the existing hoist mechanism, which operated an 8.5-foot wide by 4.75-foot tall gate. The existing mechanism entailed three pairs of 12-inch iron wheels that rolled on an iron plate. The modifications were intended to permit operation by one man.

Figure 5-1. Hamilton Wasteway Gate House, rack-and-pinion hoisting mechanism.

5.8 Northern Canal - Pawtucket Gate House[18]

The Northern Canal, which extended from the Merrimack River, just downstream from the Pawtucket Dam to the Western Canal, was designed and constructed between 1846 and 1848. The canal was intended to raise the total head of water by three feet. The Northern Canal Guard Gates, housed within the brick Guard House, control the flow of water into the canal. The ten guard, or sluice gates, were originally operated by a Francis turbine, the first turbine of this design ever constructed, that drove a system of belting and shafting (Figure 5-3, 5-4, 5-5, and 5-6). Alterations to the guard gates since 1848 include:

Figure 5-4. Pawtucket Gate House, belt-and-line shaft system.

1878 main belt (96 feet long and 20 inches wide) replaced,
1881 main line shaft replaced,
1883 smaller belt pulleys replaced by friction pulleys and a clutch mechanism that permitted independent operation of each gate,
1891 turbine abandoned and hoist mechanism electrified,
1928 3 1891 electric motors replaced with a single 25-horsepower motor,
1950s 1928 electric motor replaced with a 10-horsepower motor for each gate.[19]

Figure 5-6. Pawtucket Gate House, sluice gate casings, with belt drives above.

6.0 HISTORICALLY SIGNIFICANT WATERPOWER EQUIPMENT

As noted above, it is the totality of the system of waterpower and water-control machinery at Lowell that is historically significant. Removal and replacement of individual pieces of equipment was nearly continual, from the day the system first became operational. Removal or alteration of existing equipment would constitute an adverse effect upon the qualities that make the existing system historically significant if they prevented or precluded the system from operating. Several pieces of equipment appear to be historically significant, distinct from their role as a part of the larger system. These pieces of equipment include the surviving 1870 hydraulic gate hoist system at the Pawtucket Canal Guard Locks, and the Francis turbine powered belt-and-line shafting gate operating system at the Pawtucket Gate House. The extant gate operating system at the Moody Street Feeder Gate House (Figure 6-1 and 6-2) is likely also significant in its own right.

Figure 6-1. Moody Street Gate House, gate hoisting mechanisms.

Figure 6-2. Moody Street Gate House, detail of gate hoisting mechanism

7.0 CURRENT OWNERSHIP

Boott owns, or is responsible for, the equipment located within the canal systems gatehouses and other facilities, but is not responsible for most buildings, the canal prism, lock gates, or dams. In essence, Boott is only responsible for the equipment and devices that control the flow of water through the canal system. These elements, including flashboards, gates, and their operating equipment, have been upgraded and altered on many occasions.

The 1870 hydraulic gate hoist system at Pawtucket Canal Guard Locks is likely owned in part by PLC and the Commonwealth of Massachusetts, acting through the Massachusetts Department of Recreation and Conservation (MADCR). MADCR appears to own the Francis turbine-powered belt-and-line shafting gate operating system at the Pawtucket Gate House. The extant gate operating system at the Moody Street Feeder Gate House is also likely owned by PLC.

1 Introduction and Background

Boott Hydropower, LLC (Boott or Licensee) is the Licensee, owner, and operator of the 20.2-megawatt (MW) Lowell Hydroelectric Project (Project or Lowell Project) (FERC No. 2790). Boott operates and maintains the Project under a license from the Federal Energy Regulatory Commission (FERC or Commission). The Project's existing license expires on April 30, 2023. Boott is pursuing a new license for the Project using the Commission's Integrated Licensing Process (ILP) as defined in 18 Code of Federal Regulations (CFR) Part 5.

In accordance with 18 CFR §5.15, Boott has conducted studies as provided in the study plan and schedule approved in the Commission's March 13, 2019 Study Plan Determination (SPD) for the Project.[1] This report describes the methods and results of the approved Operation Analysis of the Lowell Canal Study.

1.1 Project Description and Background

The Lowell Project is located at river mile (RM) 41 on the Merrimack River in the City of Lowell in Middlesex County, Massachusetts, with an impoundment extending approximately 23 miles upstream into Hillsborough County, New Hampshire. The existing Lowell Project consists of:

1) A 1,093-foot-long, 15-foot-high masonry gravity dam (Pawtucket Dam) that includes a 982.5-foot-long spillway with a crest elevation of 87.2 feet National Geodetic Vertical Datum 1929 (NGVD 29) topped by 5-foot-high, pneumatically-operated crest gates deployed in five independently-operable zones;
2) A 720-acre impoundment with a normal maximum water surface elevation of 92.2 feet NGVD 29;
3) A 5.5-mile-long canal system which includes several small dams and gatehouses;
4) A powerhouse (E.L. Field) which uses water from the Northern Canal and contains two turbine-generator units with a total installed capacity of 15.0 MW;
5) A 440-foot-long tailrace channel;
6) Four powerhouses (Assets, Bridge Street, Hamilton, and John Street) housed in nineteenth century mill buildings along the Pawtucket, Hamilton, and Eastern canal systems containing 15 turbine-generator units with a total installed capacity of approximately 5.1 MW;

[1] The Commission issued a Revised Process Plan and Schedule on June 12, 2020.

7) A 4.5-mile-long, 13.8-kilovolt transmission line connecting the powerhouses to the regional distribution grid;

8) Upstream and downstream fish passage facilities including a fish elevator and downstream fish bypass at the E.L. Field powerhouse and a vertical-slot fish ladder at the Pawtucket Dam; and

9) Appurtenant facilities.

At the normal pond elevation of 92.2 feet NGVD 29 (crest of the pneumatic flashboards), the surface area of the impoundment encompasses an area of approximately 720 acres. The gross storage capacity between the normal surface elevation of 92.2 feet and the minimum pond level of 87.2 feet is approximately 3,600 acre-feet.

The Project operates in a run-of-river (ROR) mode using automatic pond level control capability of the E.L. Field Powerhouse and has no usable storage capacity. Boott normally operates the Project to maximize flow through the available units at the E.L. Field Powerhouse, then routes any additional flows through the Pawtucket Canal system. The E.L. Field turbine-generator units are more efficient and operate at a higher head than the older canal units and are, therefore, the priority first-on, last-off units in the Project operations scheme. When river flows exceed the hydraulic capacity of the E.L. Field units (approximately 3,300 cubic feet-per-second [cfs] per unit or 6,600 cfs for both units), excess flows up to approximately 2,000 cfs are routed through the downtown canal system and to the canal units. Any flows in excess of approximately 8,600 cfs (6,600 cfs at E.L. Field plus 2,000 cfs via canals) are passed over the Pawtucket Dam spillway. Pursuant to Article 37 of the existing FERC license, the Project maintains a minimum flow of 1,990 cfs or inflow, whichever is less, as measured immediately downstream from the Project.

On December 2, 2020, Boott filed a Draft License Application (DLA) with the Commission pursuant to 18 CFR §5.16(a). As described in the DLA, Boott is proposing to remove the four canal power stations (Assets, Bridge Street, Hamilton, and John Street) and associated canal infrastructure from the new FERC license. Operation of the canal units is no longer economically feasible, and Boott is not proposing to continue generation at these four developments. Boott will continue to manage the canal structures, water levels, and flows using best practices and consistent with current agreements with the National Park Service and other stakeholders.

2 Study Goals and Objectives

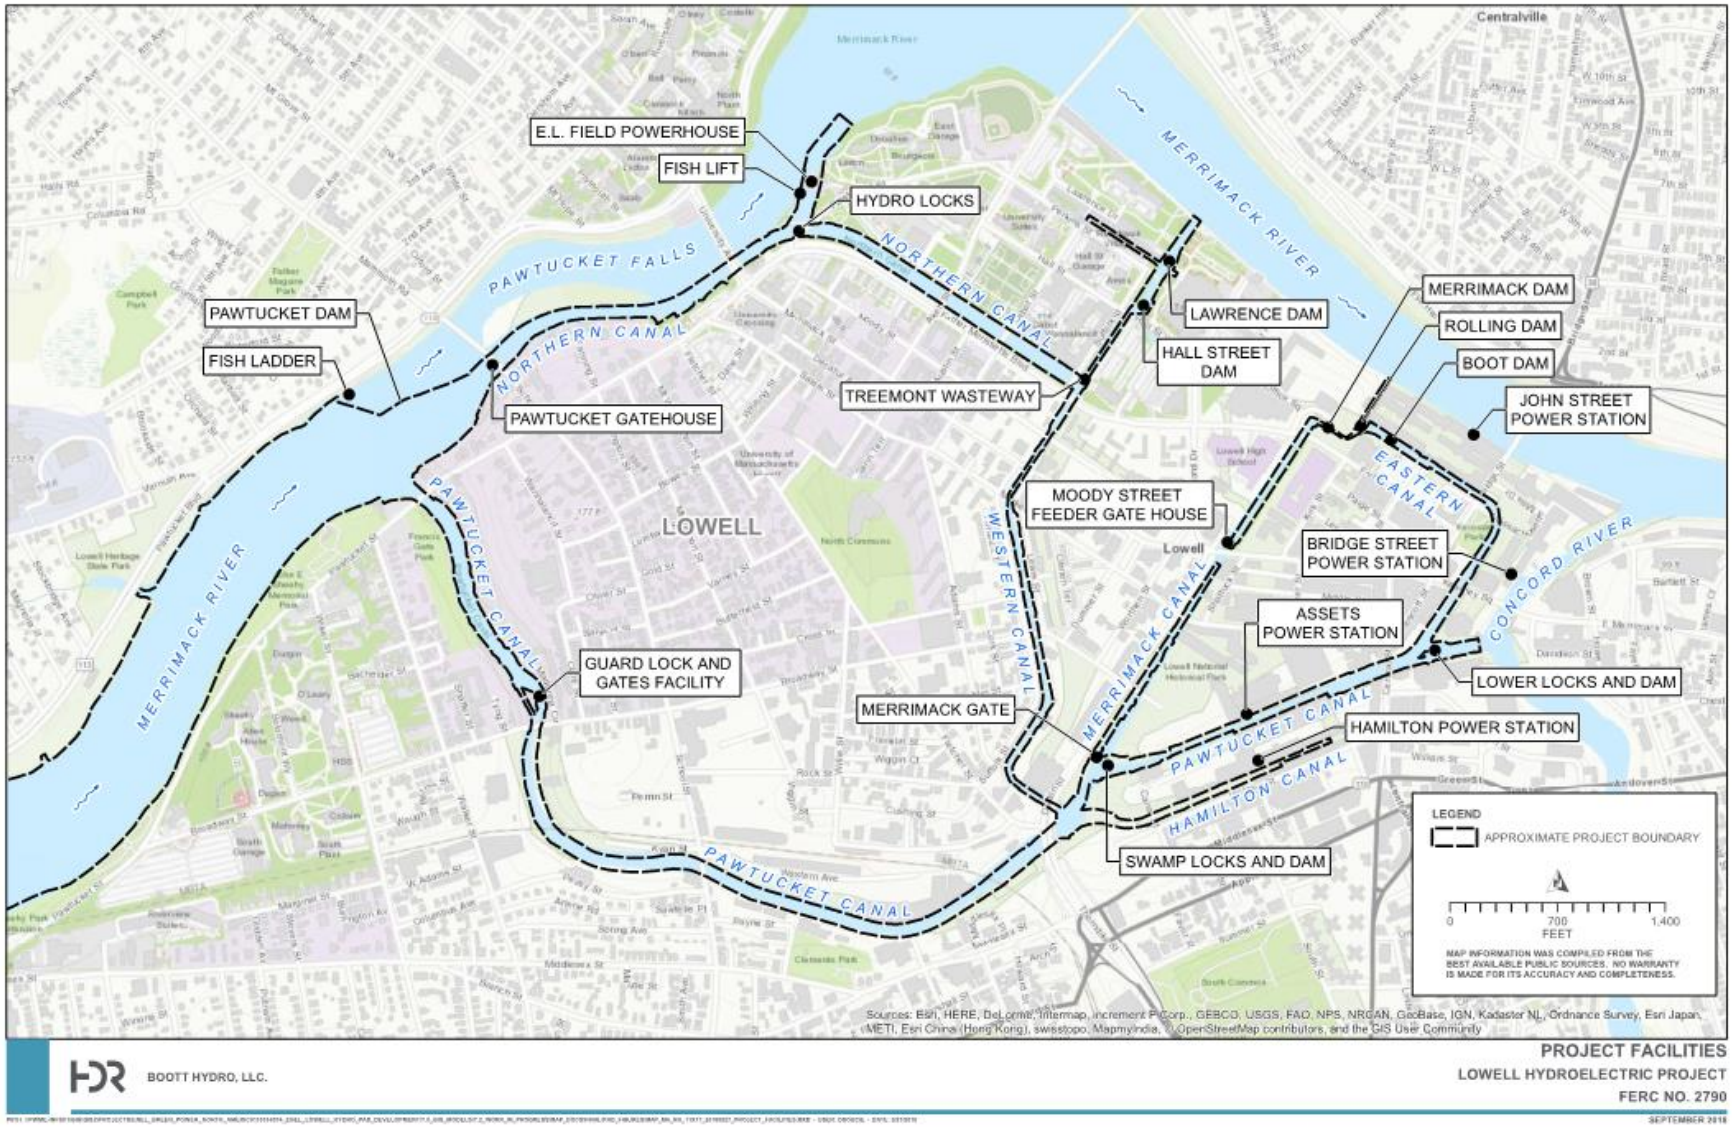
The goal of this study is to understand the operations of the Project's canal system. The specific objective of this study is to describe, to the extent possible, the operations of the canal system, which include, but are not limited to:

- How all of the canal units interact with the main units at the E.L. Field Powerhouse;
- How the canal units are sequenced;
- How often each of the canal units operate;
- The prioritization sequence of canal unit operations; and
- The amount of time the canal units are operated during the downstream passage season.

3 Study Area

The study area for the Operation Analysis of the Lowell Canal Study includes the Project's canal system and powerhouses located in the City of Lowell (Figure 3-1).

Figure 3-1. Existing Project Boundary and Facilities of the Lowell Canal System



4 Methodology

4.1 Literature Review

Boott conducted a desktop file review to examine current Project operational protocols and historical canal operations data. The canal units have experienced repeated maintenance issues, and generation is marginal, inefficient, and uneconomical under current conditions. Several of the canal system units have experienced prolonged outages in recent years, and the canal system as a whole has not been operated for purposes of generation in more than a year.

Historically, it has not been Boott's practice to log or otherwise record which of the individual canal units or powerhouses were in operation on a daily basis. As such, Boott does not have records of when individual canal powerhouses or units were operating. In general, operational data for the canal system is limited, and recent changes in both Project ownership and staffing have further compounded this issue.

To address the goals and objectives of this study, Boott reviewed data from a 10-year period of typical canal unit operations from 1998 – 2007. Data from this period was utilized in this analysis as it represented a relatively normal period of canal operations in which many (although not necessarily all) of the canal units were available for dispatch at Merrimack River flows in excess of 6,600 cfs capacity of the E.L. Field Powerhouse units. While the dataset does not indicate which specific units or powerhouses were operating, it does include aggregate records of generation (in kilowatts [kW]) for the downtown canal system recorded at 08:00 AM on a daily basis for the period of record. This data can be used to estimate how often canal units were operated on an annual basis and during downstream passage seasons. Because generation was reported in the aggregate, it is not possible to determine specifically which units or combination of units were in operation on a daily basis. Similarly, the dataset provides only a "snapshot" of daily generation at 08:00 AM; therefore, the data does not provide information on intra-daily changes in generation. However, Boott believes that this dataset provides a means of characterizing generation trends in the Project's canal system annually and for downstream passage seasons.

5 Study Results

5.1 Project Generating Units

At present, the Project includes a total of 17 generating units, including two units at the E.L. Field Powerhouse and 15 units at the downtown canal powerhouses. Generating unit characteristics are summarized in Table 5-1.

Table 5-1. Lowell Project Generating Unit Characteristics

Powerhouse	Unit #	Type	Size (Inches)	Speed (RPM)	Net Head (Feet)	Flow Rate (cfs)	Power (HP)	Power (kW)
E. L. Field	1	Fuji Horizontal Full Kaplan	152.4	120	39	3,300	11,540	7,506

John Street	6	Allis Chalmers Single Runner	72	100	21	1,000	1,925	1,200

5.2 Project Operations and Unit Dispatch Sequence

5.2.1 General Project Operations

As noted above, the Project operates in a ROR mode with no usable storage capacity. The two generating units at the E.L. Field Powerhouse are the most efficient units and are, therefore, the priority first-on, last-off units. It has been Boott's practice to dispatch the canal units when Merrimack River flows exceed the combined 6,600 cfs hydraulic capacity of the units at the E.L. Field Powerhouse. At flows higher than 6,600 cfs, Boott would typically divert up to 2,000 cfs to the canal units. Flows higher than 8,600 cfs (the combined capacity of the E.L. Field Powerhouse and the canal units) are spilled over the Pawtucket Dam spillway and into the Project's bypass reach.

5.2.2 Canal Unit Dispatch Sequence

In general, the canal unit dispatch sequence is intended to maximize the efficiency of units. Due to the imbalance of unit flow capacities between the units along the Hamilton Canal and the lower Pawtucket and Eastern canals, the Hamilton units would generally be the first units to be dispatched at Merrimack River flows in excess of 6,600 cfs. The Bridge Street units along the lower Pawtucket Canal and the John Street units along the Eastern Canal would then typically be sequenced to match the operating Hamilton canal units.

Notwithstanding this ideal unit dispatch sequence, Boott notes that the canal units have not been operated regularly in many years due to maintenance issues and other factors. In practice, the historical sequence for individual unit dispatch in each canal powerhouse has varied considerably depending on maintenance issues and unit operability. Historically, operators evaluated individual units based on flow conditions, operating efficiency, safety factors, and maintenance conditions prior to dispatching units for generation. As noted above, the canal units have not been operated in more than a year.

5.2.3 Historical Canal Unit Operations

As discussed in Section 4.1 of this study report, there is limited historical operations data available for the Project's existing downtown canal units. Boott analyzed aggregate canal unit generation data from a 10-year period of typical canal operations (1998 – 2007) to characterize operation of the Project's canal units. Boott also analyzed canal unit operations during the May – July fish passage season for spent alosines and the August – November fish passage season for adult eels and juvenile alosines. This analysis is indicative of the percent of time the canal units would be expected to operate each month under normal operating conditions.

Based on this analysis, the Project's canal units were operated on 34 percent of days during the total period of record (January 1, 1998 – December 31, 2007). The Project's canal units were operated on 40 percent of days during the May – July fish passage

season and on 15 percent of the days during the August – November fish passage season. Table 5-2 summarizes operation of the canal units by year.

Table 5-2. Percentage of Days Canal Units were Operated by Year (1998 – 2007)

Year	Total Annual Percentage of Days Canal Units were Operated	Percentage of Days Canal Units were Operated May – July	Percentage of Days Canal Units were Operated August – November
1998	37%	54%	1%
1999	30%	7%	19%
2000	30%	38%	2%
2001	17%	24%	0%
2002	27%	49%	3%
2003	40%	36%	37%
2004	45%	35%	30%
2005	64%	78%	48%
2006	29%	53%	7%
2007	18%	30%	8%

Boott also analyzed the operations of the Project's canal units on a monthly basis for the period of record, as shown in Table 5-3.

Table 5-3. Percentage of Days Canal Units were Operated by Month (1998 – 2007)

Month	Percentage of Days Canal Units were Operated
January	31%
February	23%
March	52%
April	81%
May	62%
June	43%
July	16%
August	6%
September	12%
October	15%
November	29%
December	35%

Finally, Boott conducted an analysis to determine the total number of days per month that the canal units were operated during the 10-year period of record, as shown in Table 5-4.

Table 5-4. Number of Days Canal Units were Operated by Month and Year

6 Summary and Discussion

The Lowell Project's canal generating units have experienced maintenance issues that have prevented normal operation of the units for the past several years. Limited operational data is available for the canal units, and it has not been Boott's practice to record individual canal unit or powerhouse start/stop times or daily generation. In order to address the goals and objectives of the Operation Analysis of the Lowell Canal Study, Boott reviewed available data from a period of relatively normal canal unit operations (1998 – 2007) to characterize how often the canal units were operated on an annual basis and during the May – July and August – November downstream fish passage seasons. Based on the available data, canal unit operations varied considerably from year-to-year. In general, this can be attributed to two primary factors:

- **Merrimack River Flows:** Boott prioritizes generation at the E.L. Field Powerhouse, and the downtown canal units are not dispatched until Merrimack River flows exceed the combined 6,600 cfs hydraulic capacity of the E.L. Field Powerhouse's two generation units;
- **Unit Maintenance and Operability:** The majority of the canal units were last upgraded in the 1940s and are now almost 80 years old. These units are routinely out-of-service for maintenance or because they are simply inoperable.

As discussed in Boott's December 2, 2020 DLA for the Project, operation of the canal units is no longer economically feasible, and Boott has proposed to remove the downtown developments (Assets, Bridge Street, Hamilton, and John Street) from the Project's FERC license. Boott is not proposing to restart or continue generation at these four developments.

7 Variances from FERC-Approved Study Plan

The Operation Analysis of the Lowell Canal Study was conducted in full accordance with the methods described in the FERC-approved study plan except for the following variances:

- The approved study plan directs Boott to describe how often each of the canal units operate and the amount of time canal units operate during the downstream passage season. As discussed in this study report, it has not been Boott's practice to record individual canal unit operations or document unit start/stop times. Accordingly, Boott reviewed and analyzed records from a period of relatively normal canal unit operations that reflect a daily "snapshot" of aggregate canal unit generation.

1 Introduction

1.1 Purpose

The sections below detail the methods used to develop the Computational Fluid Dynamics (CFD) model and provide the requested data for the Lowell Hydro Fish Passage CFD study. This technical memo describes the numerical methods, model geometry, mesh development, boundary conditions, and results.

1.2 Background

The Federal Energy Regulatory Commission's (FERC) June 15, 2018 Scoping Document 1 identified the environmental resource issues at the Lowell Hydroelectric Project (Project) (FERC Project No. 2790) for analysis. The U.S. Fish and Wildlife Service, National Marine Fisheries Service, Massachusetts Division of Fisheries and Wildlife, and New Hampshire Fish and Game Department submitted formal requests for a CFD Modeling Study (Study) of the Project's fish passage facilities.

The goal of the Study is to determine the flow field conditions that exist in and around the Project's fish passage facilities, including around the fishway entrances, within fishway structures, and in the E.L. Field Powerhouse forebay. Information derived from this Study may be used in conjunction with telemetry and other studies performed for the Project relicensing (American Eel Passage Downstream Study, Juvenile Alosine Downstream Study, and Adult Alosine Passage Study Upstream and Downstream) to analyze fish behavior in response to hydraulics. This is anticipated to aid in the interpretation of preferable conditions for the guidance of migrating fish to and through the fish passage facilities.

The study area includes a portion of the Pawtucket Dam E.L. Field Powerhouse forebay, tailrace, and fish lift, the bypass reach in the vicinity of the Pawtucket Dam fish ladder entrance, and within the fish ladder.

2 CFD Model Development

2.1 Model Description

FLOW-3D is a commercially available software developed and supported by Flow Science, Inc. that is capable of solving the three-dimensional (3D) Unsteady Reynolds Averaged-Navier Stokes (URANS) equations. The software utilizes a Volume of Fluid method to calculate the free surface within the domain (Hirt & Nichols, 1981). The package contains the meshing module (pre-processor), solver, and post-processor. FlowSight was used to produce the results presented below and is provided with the FLOW-3D software package.

2.1.1 Modeling Approach

The governing equations used in Flow-3D are provided in the software user's guide (Flow Science, Inc, 2019). The software solves fully URANS equations on structured grids. Model fitted meshes were developed for the Pawtucket Dam fish ladder, E.L. Field Powerhouse forebay and E.L. Field Powerhouse tailrace. Known water surface elevations (WSE) and/or known flowrates were applied to the upstream boundaries of the CFD models. Applying the known WSE reduces the complexity of the URANS equations.

PRESSURE SOLVER OPTIONS

Two numerical schemes are available for the pressure solver with multiple options. Explicit and implicit solvers are available. Within the implicit solver, multiple options are available. Limited compressibility models can be toggled to relax the constraints of the pressure solver for cases where solution stability is an issue. The implicit pressure solver was applied to the model for the results presented below.

TURBULENCE MODELS

Various one (Prandtl Mixing Length and Turbulent Energy Model) and two equation (k-ε, k-ω, and RNG) turbulence models are available in FLOW-3D. A large eddy simulation model is also available for selection depending on the type of flow expected and desired flow feature resolution. The Renormalized Group (RNG) model was selected and is an applicable closure for the CFD Study based on anticipated flow patterns (Orszag & Yakhot, 1986).

MODEL LIMITATIONS

The CFD model is limited in the data it can accurately produce. Some hydrodynamic features are not accurately modeled with the selected solver and turbulence closure. For example, recirculation patterns and vortices are approximate in size and strength. Results within this memorandum are subject to the inputs at the time of the study.

2.2 Model Geometry

HDR developed a topographic Digital Elevation Model (DEM) using Geographical Information Systems (GIS). All geo-processing of the following data sources was achieved using the ArcMap (Esri) application's 3D analyst geo-processing tools.

A single DEM was created from the following data sources:

- Ortho imagery Light Detection and Ranging (LiDAR) based elevation data collected by Normandeau Associates, Inc. (Normandeau) provided in coordinate system Universal Transverse Mercator (UTM) Zone 19N, North American datum (NAD) 83 2011, units meters, North American vertical datum of 1988 (NAVD 88), units meters.
- Bathymetry depth points collected by Normandeau from three areas; 1) just upstream of the main dam fish ladder, 2) the power canal, and 3) the powerhouse tail race. Data provided in coordinate system UTM Zone 19N, NAD 83 2011, units meters, vertical datum NAVD 88, units feet.

- LiDAR acquired from United States Geological Survey (USGS) LASer file (LAS) format 2011. Data provided in coordinate system UTM Zone 19N, NAD 83, units meters, vertical datum NAVD 88, units meters.

The domain for each of these data sources is presented on Figure 2-1.

Most of the coverage area required for CFD modeling was comprised of data received by Normandeau as a randomly spaced point cloud xyz file. The xyz file was derived from remotely sensed survey in NAVD 88 vertical datum. These data were transformed as a discrete point feature class using "American Standard Code for Information Interchange (ASCII) 3D to Feature Class" geo-processing tool. Both the horizontal coordinate system (UTM 83 meters) and vertical units (NAVD 88 meters) were maintained. Figure 2-1 shows the Project reach and model terrain data sources.

The vertical units for the bathymetric survey data points were converted from feet (ft) to meters in order to match the vertical units of the larger areas of the overall CFD model area. A final step of converting the terrain to National Geodetic vertical datum (NGVD 29) was performed by adding 0.242 meters (0.793 ft) to the vertical units.

In several small overbank areas upstream of the fish ladder and along the east bank of the power canal and tailrace, additional terrain data were needed to provide additional detail; USGS LiDAR randomly spaced point cloud data was utilized. These USGS LiDAR derived files were converted from LAS to points using geo-processing tools "LAS Dataset to triangulated irregular network (TIN)" then "TIN Node".

In the areas of the fish ladder and fish elevator, polygon feature class were created to depict a flat area higher in elevation (El.) than the bottom of the Sterolithography file in Standard Tessallation Language (STL) file format in order to exclude water from ‘seeping’ between the final terrain DEM and the STL.

All components as described above were combined into a TIN using the "Create TIN" geo-processing tool. This resulting TIN was then converted to a final DEM raster using "GIS software within ArcMap (ESRI). The final step was to convert the .tiff raster to ASCII file "Raster to ASCII" for final import into the CFD model.

The fish ladder and E.L. Field Powerhouse structures were created in AutoCAD and exported to an STL in NGVD 29 vertical coordinates. The STLs and ground surface were rotated to align to an arbitrary vertical position. The rotation allows the structure location to align with the orthogonal mesh elements required for the solver. The rotated model reduces the number of mesh elements necessary to define the features within the model domain.

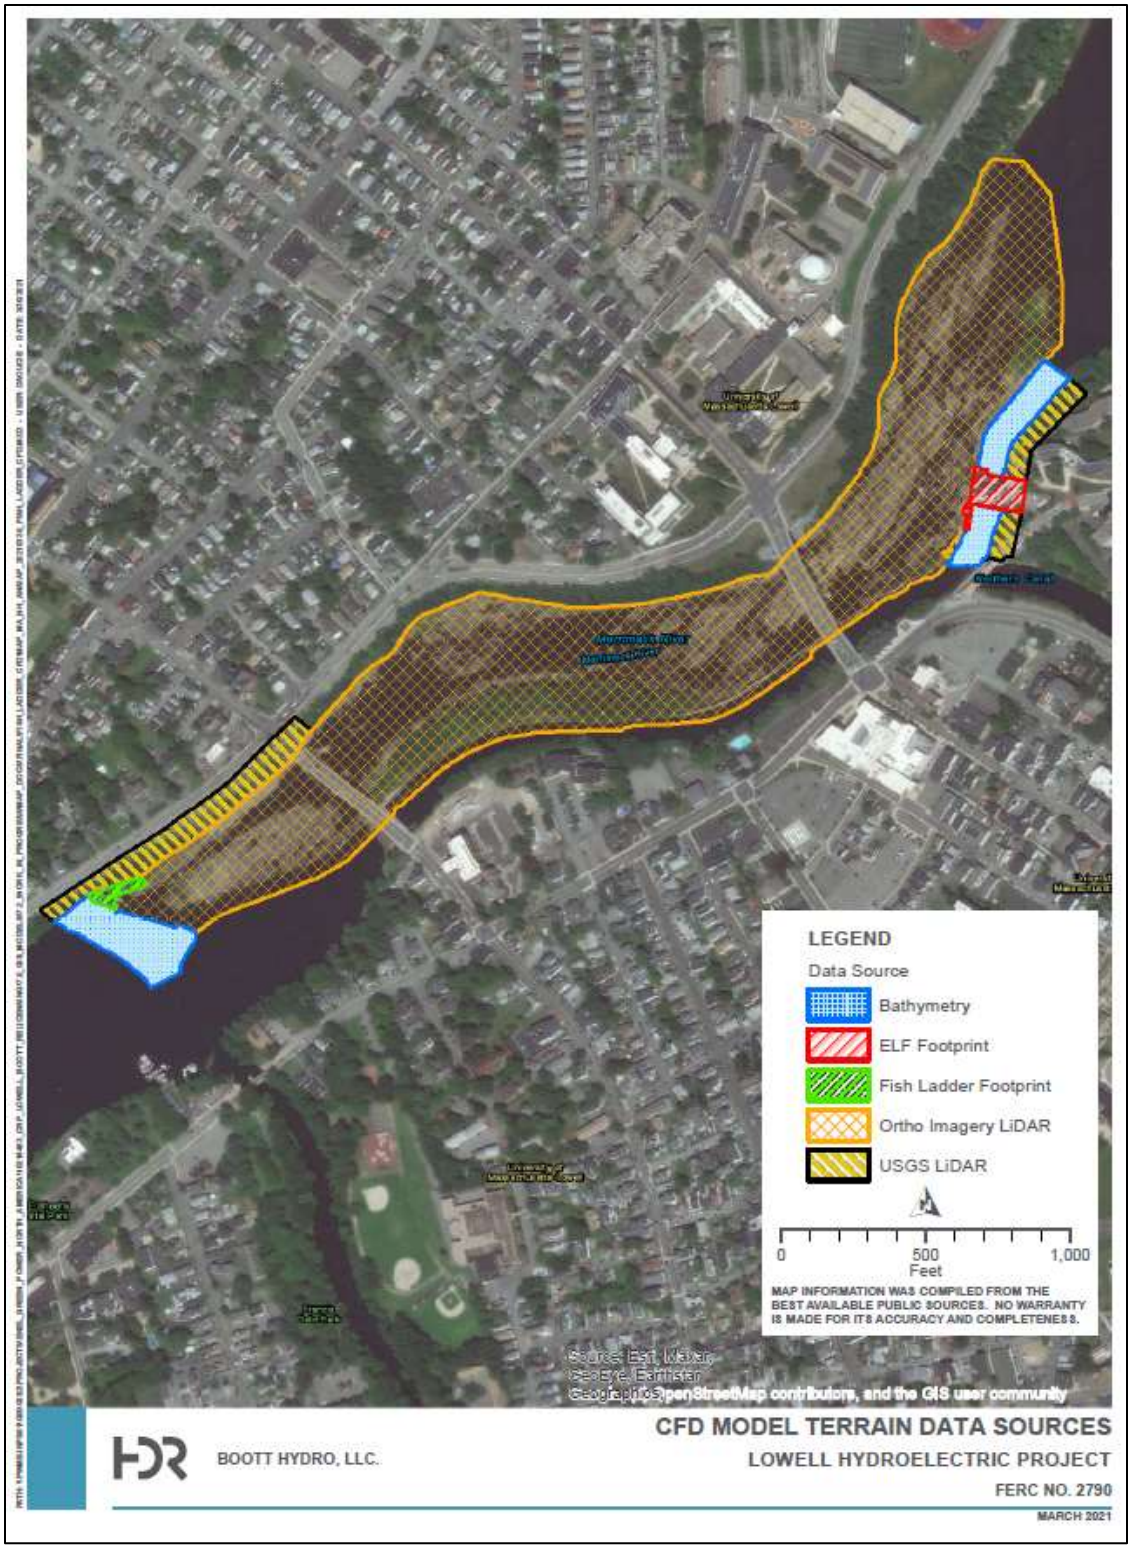

Figure 2-1: Data Sources Used in CFD Modeling Study Terrain Model Development

3 Mesh Development

The pre-processor for FLOW-3D works with orthogonal elements. The model topography and features were rotated to capture significant features with fewer elements. A balance between mesh density and computational time was desired. Several iterations of mesh density were performed, providing the basis for a mesh sensitivity analysis. A multi-block approach was utilized to build the model domain. The use of a multi-block domain allows multiple mesh sizes to be used throughout the domain. Each mesh block conformed to best practice guidelines provided by Flow Science (Flow Science, Inc, 2019).

3.1 Fish Ladder

3.1.1 Mesh Sensitivity Study

Multiple meshes of the fish ladder were analyzed to determine if the solution was grid independent. The first grid tested used 0.8-ft spacing in all three axial directions (coarse). After completion of the first simulation, the grid was refined to use a 0.4-ft spacing in all three axial directions (standard). The 0.4-ft mesh was further refined in a third test to limit the mesh spacing to 0.2-ft (refined). Figure 3-1 shows the meshed blocks with 0.4-ft spacing.

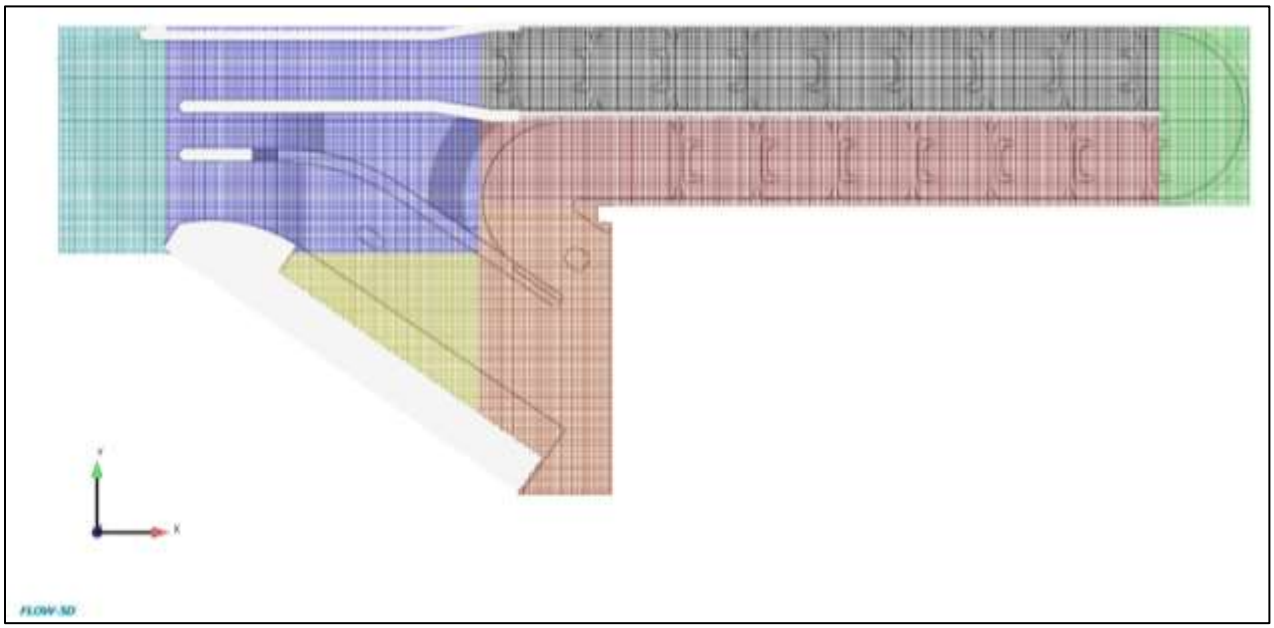

Figure 3-1: Fish Ladder Mesh Blocks (0.4-ft grid spacing)

During the mesh development stage of the CFD Study, multiple runs using identical boundary conditions were completed to determine the sensitivity to mesh parameters. Virtual probes measuring depth and velocity were placed throughout the fish ladder to measure the effects of the mesh refinement on model hydraulics.

The standard 0.4-ft grid spacing was used as a base for the final model. Further refinement to the vertical spacing resulted in a 0.2-ft vertical mesh size in the fish ladder. Additional refinements to the fish ladder mesh were assigned to the inflow area to improve model stability. WSE differences were minimal, and depth and velocity differences were minor between the refined and standard grid spacing.

3.1.2 Adding Terrain and Fish Ladder Features

Following the mesh sensitivity study, the Merrimack River bathymetry and Lowell Hydro Dam features were added upstream and downstream of the fish ladder. The combined bathymetry, dam, and fish ladder geometry is shown on Figure 3-2. It should be noted that the best available LiDAR data was used to capture the downstream bathymetry. Water levels in the Merrimack River at the time of LiDAR collection were such that only the five most up-stream weirs were captured in the terrain data. These weir geometries, and the face of the dam, were then refined within Flow-3D using existing as-built drawings as a guide. The bypass weirs were added to the model to provide a visual representation of potential flow features and not intended for detailed analysis.

A meeting between HDR and Boott Hydropower, LLC was held on March 2nd, 2021. Several updates to the fish ladder geometry were requested during the meeting and the following features were added:

- Baffles (2-ft and 4-ft) were installed along the inside and outside runs (facing downstream), respectively. These baffles sit approximately 6 inches above the floor of the fish ladder (shown on Figure 3-3).
- The inside section of the fish ladder exit has been sealed (shown on Figure 3-3).

The model extends from the upstream entrance of the fish ladder approximately 1000 ft downstream to the Mammoth Road Bridge.

As the fish ladder was the area of interest, the combined model mesh was refined to 0.4-ft grid spacing in the x- and y-axial directions and 0.2-ft grid spacing in the z-axial direction in the fish ladder vicinity. To facilitate reasonable computation run times, the mesh refinement was decreased from 0.4-ft, to 0.8-ft, and finally 1.6-ft grid spacing in the x- and y-axial directions moving away from the ladder. For the bypass reach blocks (non-fish ladder mesh blocks), the z-axial mesh spacing was a constant 0.4-ft. The three refinement levels are shown on Figure 3-4 as red (0.4-ft), green (0.8-ft) and blue (1.6-ft grid spacing) areas.

3.1.3 Bypass Weir Modifications

After discussions of preliminary results for the bypass area, a request to modify the bypass weirs to reflect the recommended configuration was made. The modifications to the bypass weirs were done to match the surveyed elevations of the recommended configuration. The surveyed elevation was originally provided on April 1st, 2021 (US Fish and Wildlife, 2014). The modified weir configuration was confirmed on a call with the Zone of Passage working group on June 21, 2021.

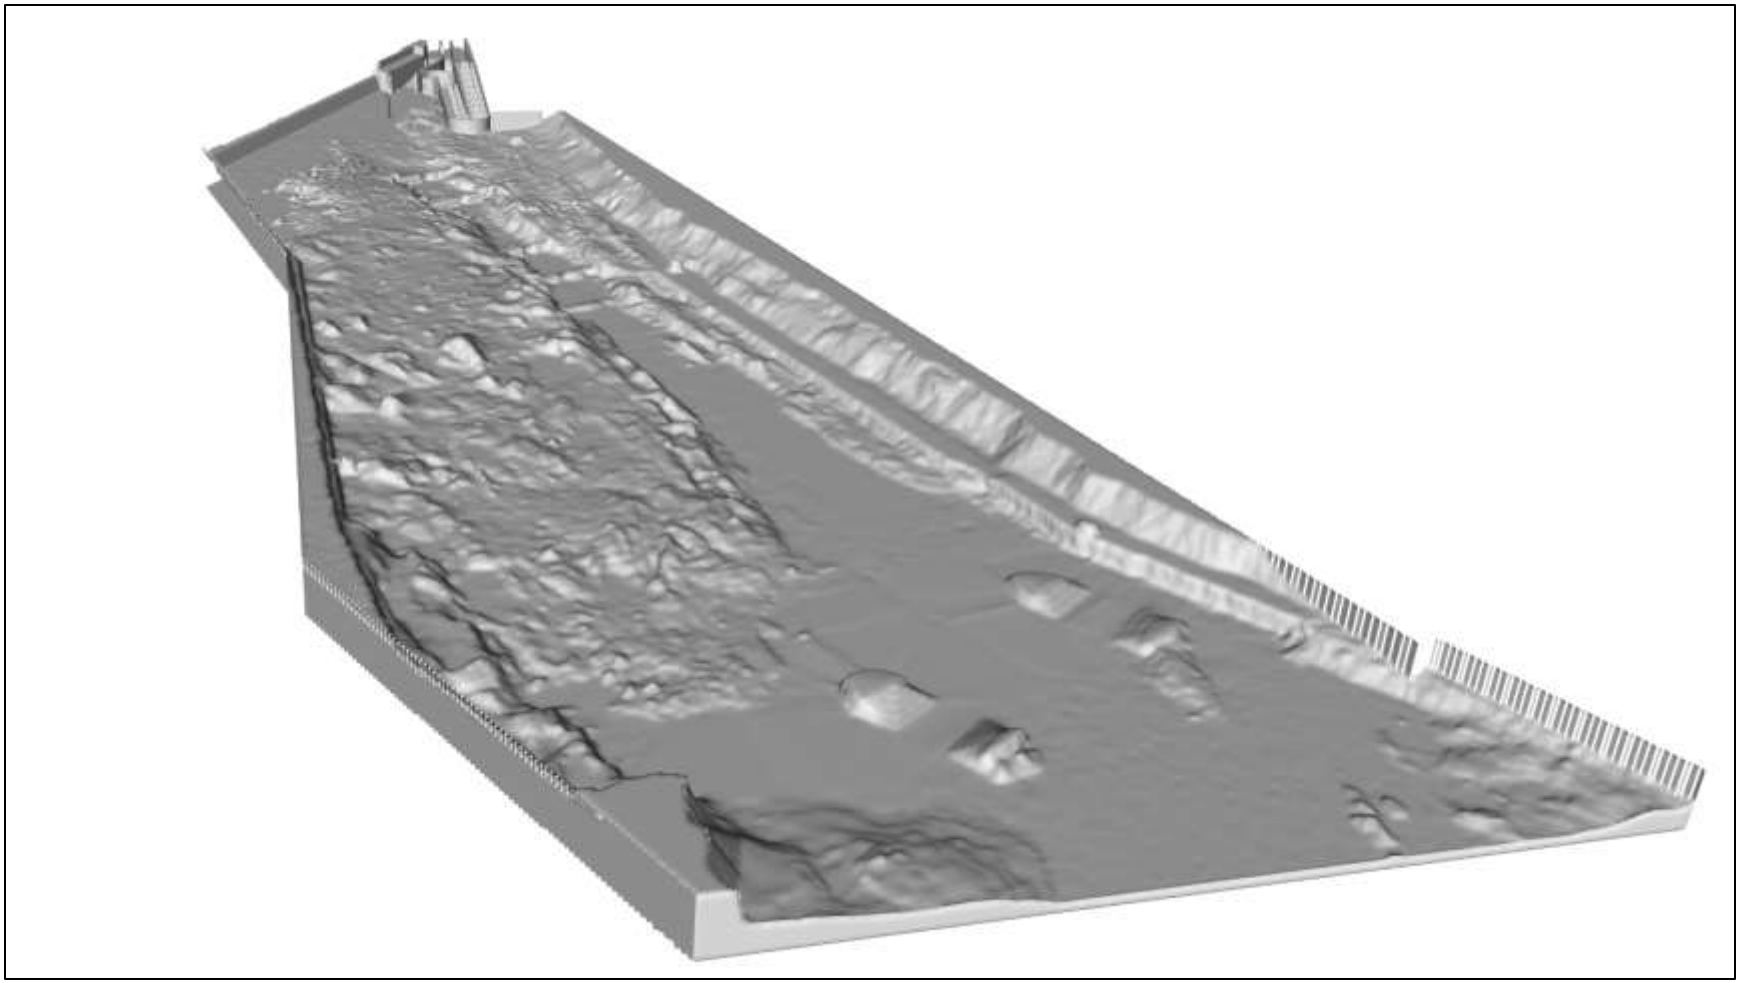

Figure 3-2: Combined Fish Ladder, Dam, and Bathymetry Geometry

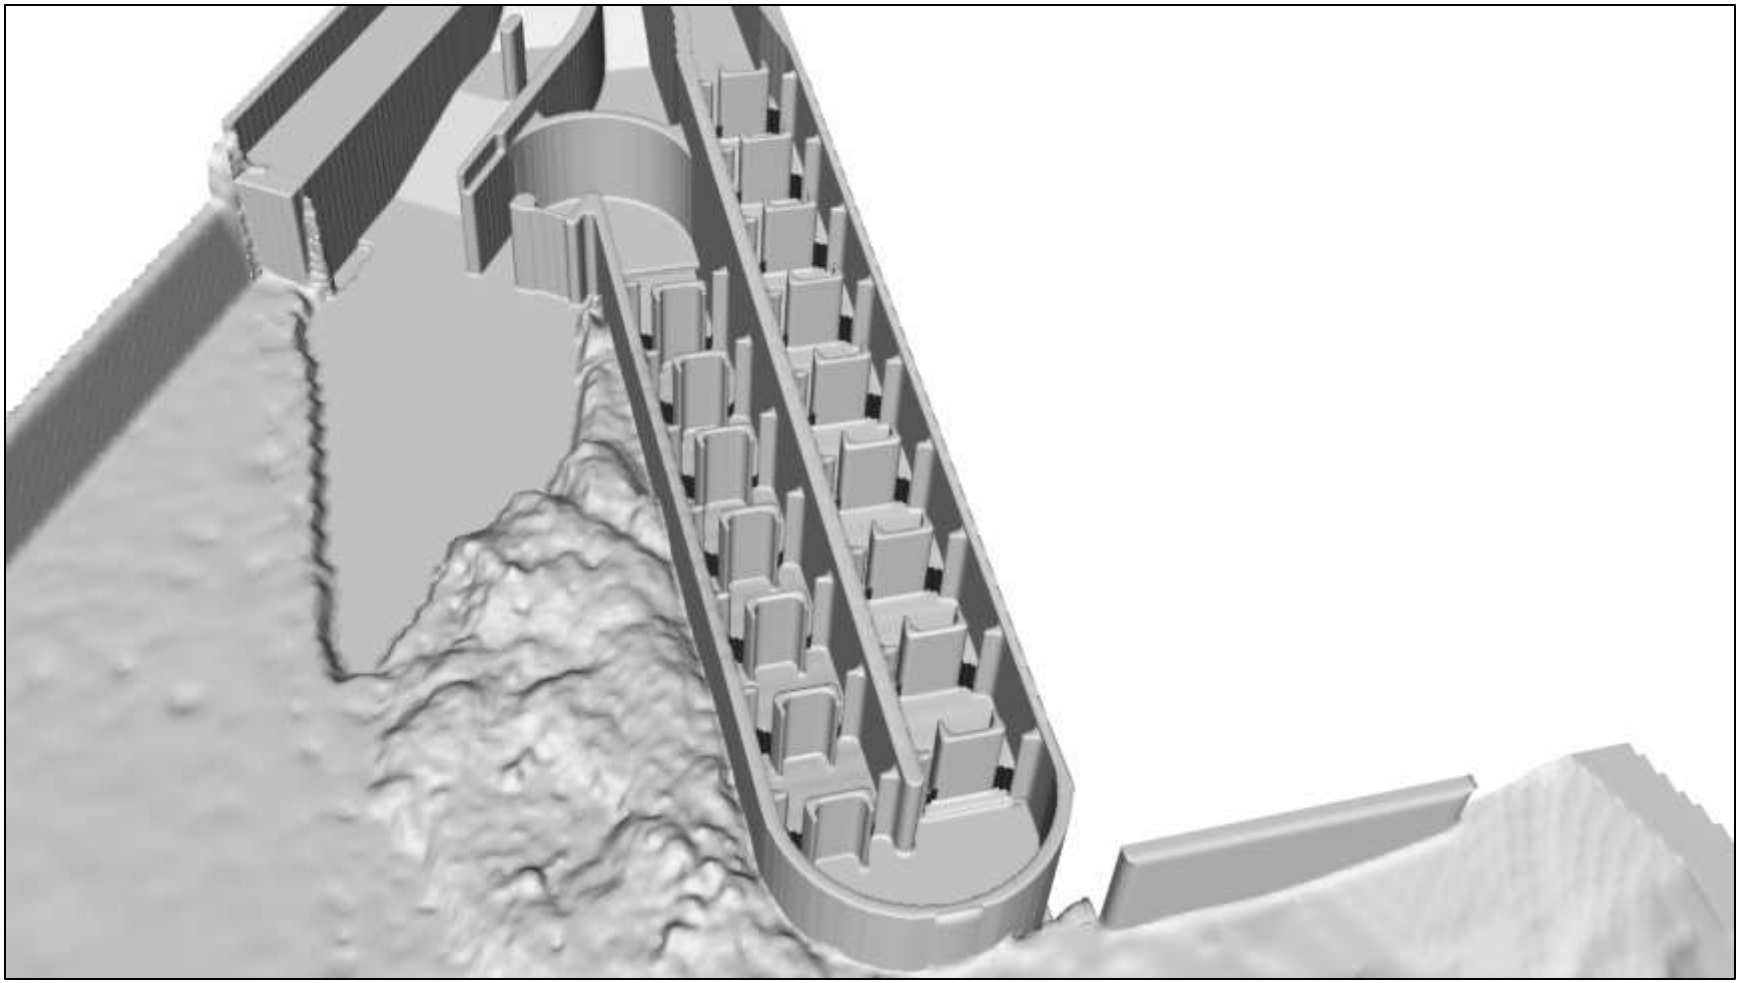

Figure 3-3: Fish Ladder Baffles (black) and Sealed Exit Section

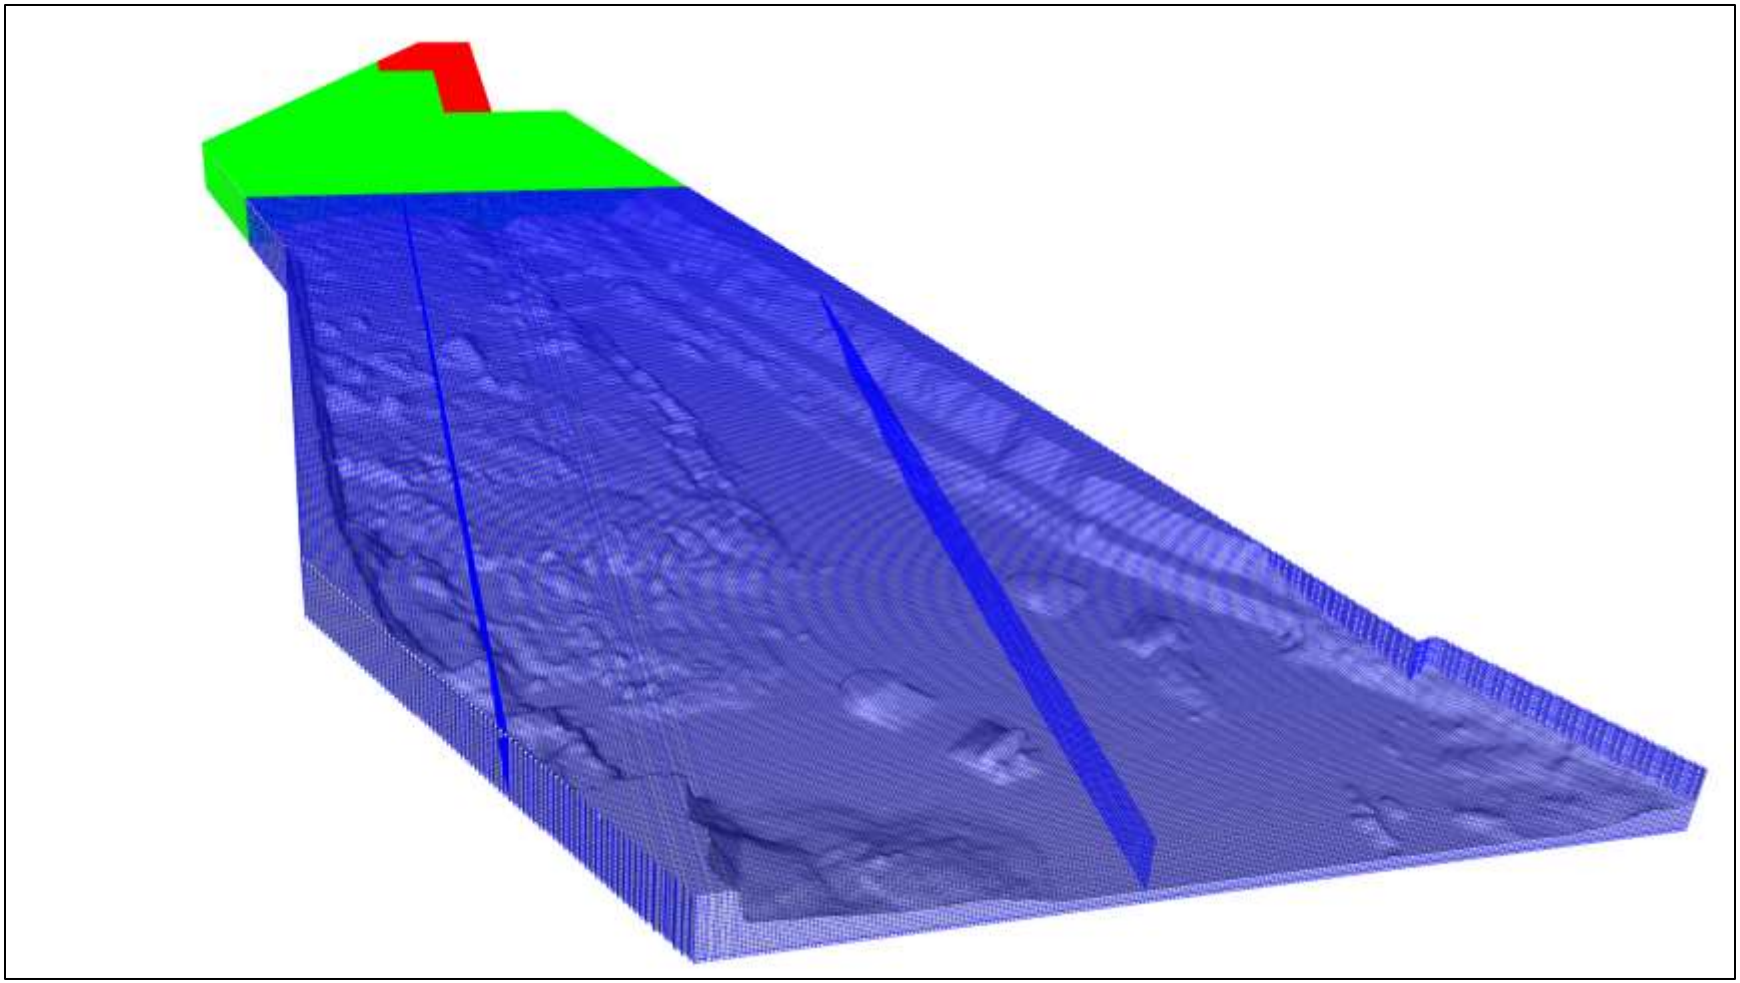

Figure 3-4: Combined Fish Ladder, Dam, and Bathymetry Mesh Refinement Zones

3.1.4 Model Scenarios

Table 3-1 lists the model analysis scenarios for the fish ladder model. The three simulations feature different inflow conditions to vary the hydraulics through the reach. It was assumed the fish ladder and diffuser flow was consistent between all three simulations. The flow (in cubic ft per second [cfs]) over the crest gate was assigned to a mass source using a unit flow rate calculation to evenly distribute flow over the crest.

Table 3-1: Model Analysis Scenarios for the Fish Ladder Model

Case	Fish Ladder (cfs)	Diffuser (cfs)	Crest Weir (cfs)	Sluice (cfs)	Notes:
1	30	60	300	0	Uses 40 ft section of crest weir adjacent to fish ladder
2	30	60	0	360	N/A
3	30	60	19,310	0	5% duration (26,000 cfs) minus E.L. Field Powerhouse operating at full capacity (6,600 cfs)
3	47	60	0	360	5% duration (26,000 cfs) minus E.L. Field Powerhouse operating at full capacity (6,600 cfs)

3.2 E.L. Field Powerhouse Forebay Model

A forebay model was developed to study the hydraulics of flow to the powerhouse. The full model geometry is shown on Figure 3-5.

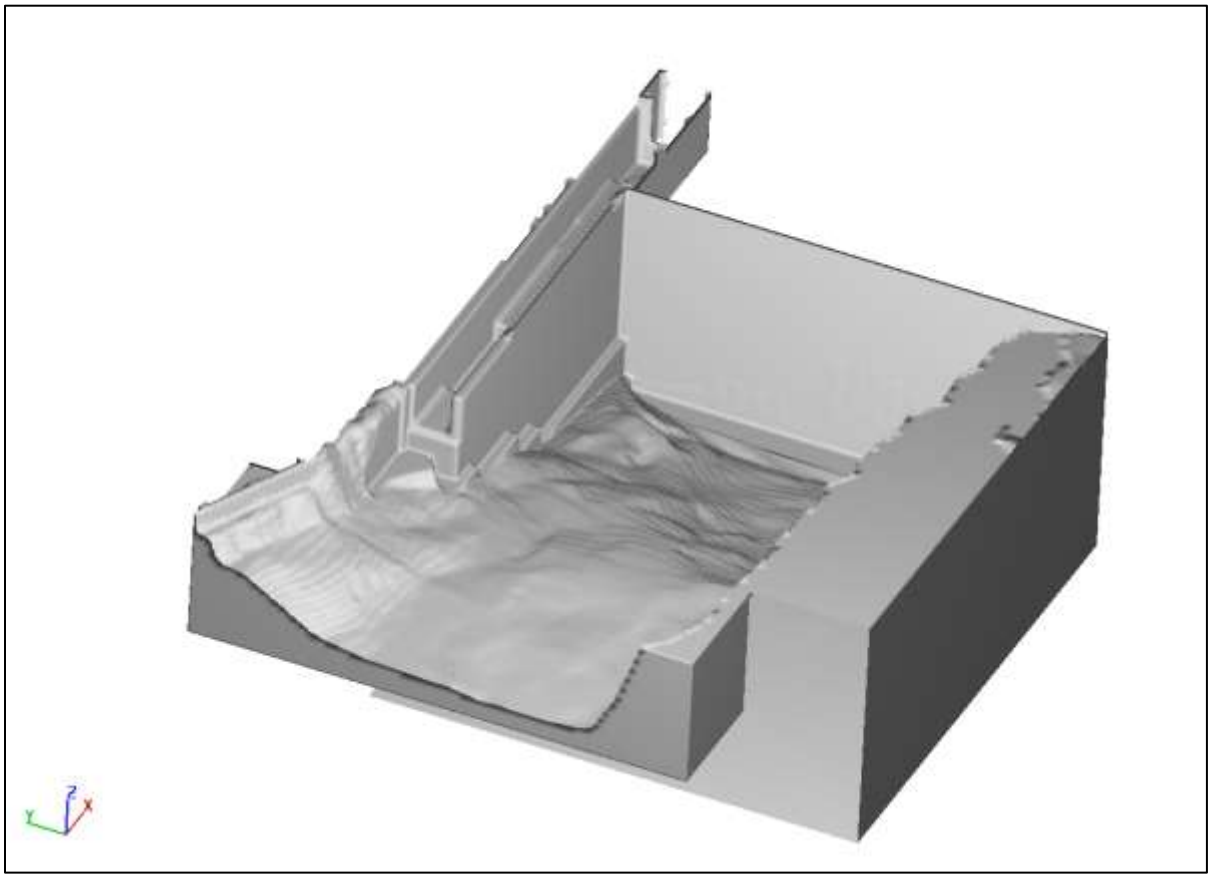

Figure 3-5: E.L. Field Powerhouse Forebay Model Geometry

3.2.1 Mesh Sensitivity Study

A mesh sensitivity study on the forebay model was completed with multiple mesh sizes. The first simulation used a 1.0-ft mesh in all three axial directions. Once the simulation was complete, the mesh was refined to use a 0.5-ft mesh.

The large recirculation patterns and low velocities resulted in similar results for the simulated meshes. The final mesh size was 0.5-ft in all axial directions.

3.2.2 Model Scenarios

Table 3-2 lists the boundary conditions for the forebay model. The forebay model used a constant WSE flow from the powerhouse channel as the upstream boundary condition. Mass sinks were used to allow flow to be removed from the powerhouse tunnels and the auxiliary water supply.

Table 3-2: CFD model scenarios for forebay model

Case	Unit 1 Discharge (cfs)	Unit 2 Discharge (cfs)	AWS Discharge (cfs)	Forebay WSE (ft, NGVD29 [NGVD88])	Notes:
1	3,300	3,300	130	91.0 [90.2]	5% exceedance flow tailwater El. (26,000 cfs)
2	1,310	1,310	130	91.0 [90.2]	75% exceedance flow tailwater El. (2,750 cfs)
3	600	600	130	91.0 [90.2]	Minimum unit operations

3.3 Tailrace Model

A tailrace model was developed to study the hydraulics of the flow leaving both the powerhouse and the auxiliary water supply (AWS). The full model geometry is shown on Figure 3-6. A detailed view of the powerhouse exits and flow directions with approximate powerhouse discharge and AWS boundaries is shown on Figure 3-7.

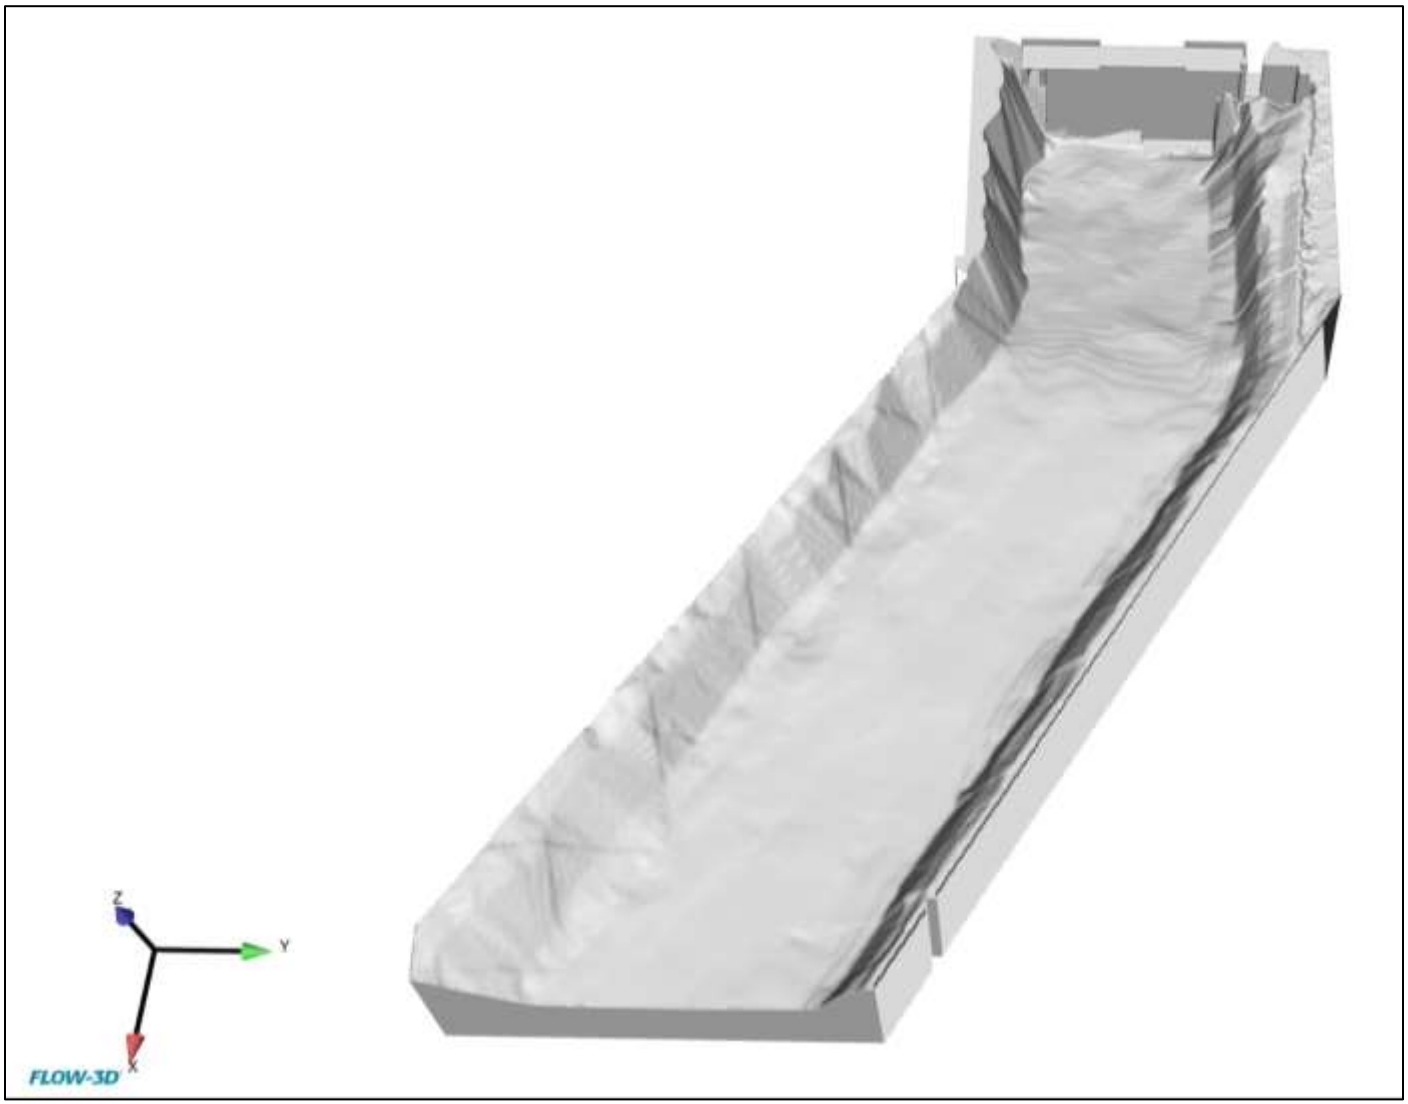

Figure 3-6:Tailrace Model Geometry

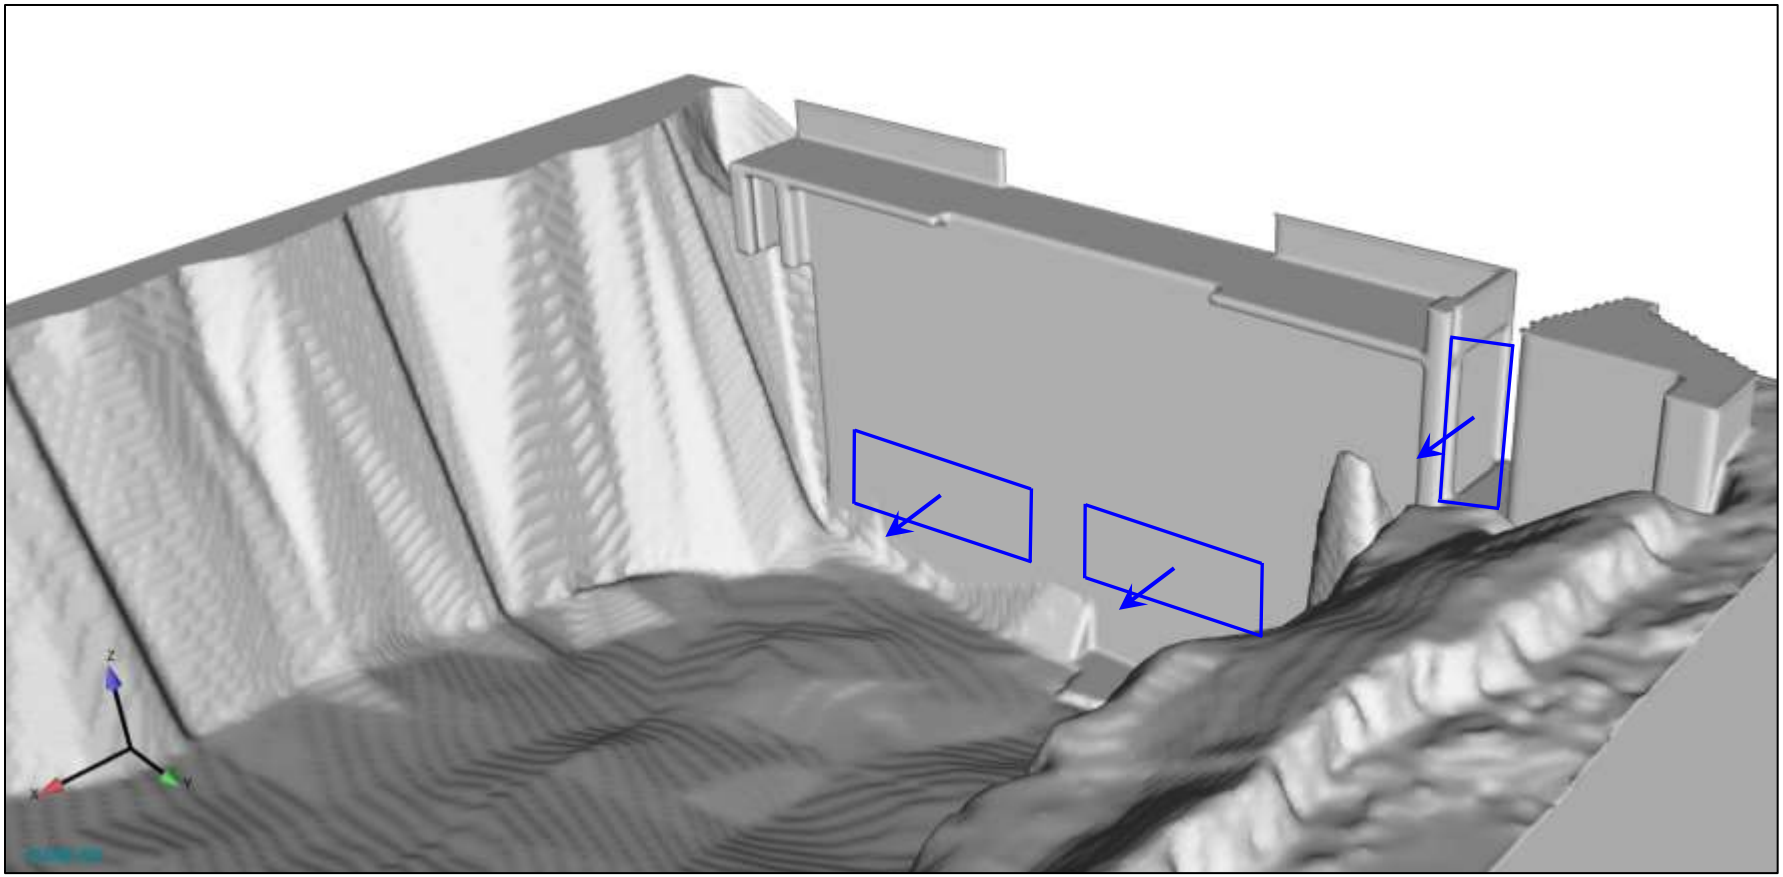

Figure 3-7:Tailrace Model Geometry, ELF Exit and Powerhouse Inflow Boundaries

3.3.1 Mesh Sensitivity Study

Multiple meshes were analyzed to determine if the solution was grid independent. The first grid tested used 1.6-ft spacing in all three axial directions. After completion of the first simulation, the grid was refined to use a 0.8-ft spacing in all three axial directions. Sensitivity to a second refinement was then analyzed. To ensure reasonable computation run times, the model mesh was then refined in the first 100 ft downstream of the powerhouse to 0.4-ft spacing in all three axial directions. The remainder of the domain was left at 0.8-ft spacing for the most refined. Figure 3-8 shows the mesh for the 0.8-ft spacing in the vicinity of the powerhouse.

A 0.8-ft mesh spacing in all directions for the entire tailrace model was chosen for the final analysis.

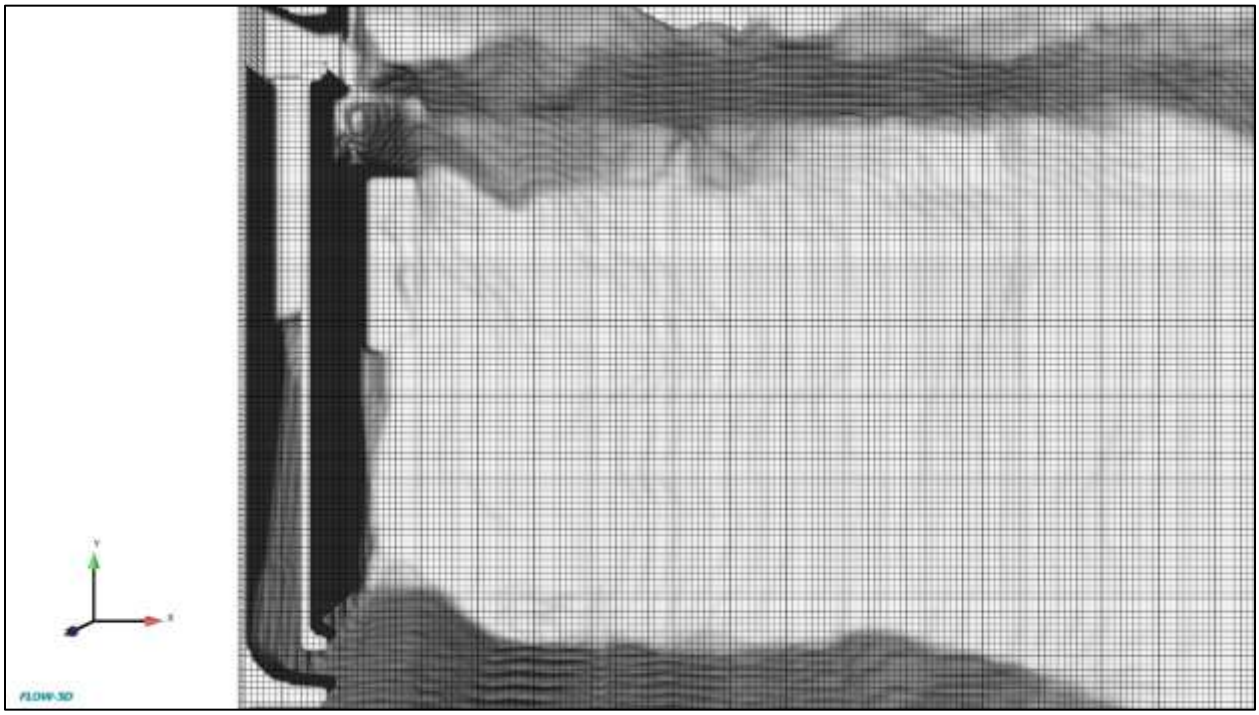

Figure 3-8: Typical Mesh Layout for Tailrace Model

3.3.2 Model Scenarios

Table 3-3 lists the boundary conditions for the tailrace model. The tailrace model used mass sources to add flow from the powerhouse units and the auxiliary water supply.

Table 3-3: CFD model scenarios for tailwater model

Case	Unit 1 Discharge (cfs)	Unit 2 Discharge (cfs)	AWS Discharge (cfs)	Tailwater WSE (ft, NGVD29 [NAVD88])	Notes:
1	3,300	3,300	100	58.36 [57.57]	5% exceedance flow tailwater El. (26,000 cfs)

Case	Unit 1 Discharge (cfs)	Unit 2 Discharge (cfs)	AWS Discharge (cfs)	Tailwater WSE (ft, NGVD29 [NAVD88])	Notes:
2	3,300	3,300	100	53.17 [52.38]	50% exceedance flow tailwater El. (6,800 cfs)

3.4 Model Approach

3.4.1 Boundary Conditions

Boundary conditions for the CFD model were applied through multiple boundary types, as listed below:

VOLUME FLOW INLET

The volume flow inlet allows a specified volume of flow to enter the model and was used at the upstream boundary of the model. A directional vector was applied to the inflow. The water surface was known and was specified for the inflow boundary condition.

PRESSURE INLET/OUTLET

The pressure boundary conditions specify a known pressure and/or WSE for the boundary.

MASS MOMENTUM SOURCE/SINK

The mass momentum source/sink allows a specified volume of flow to enter/exit the model at a specific location not associated with a mesh block boundary. This boundary type was used at the crest weir, auxiliary water supplies (AWS) and powerhouse inlet/outlet. A directional vector and uniform velocity distribution were applied to the inflow.

WALL

The boundary type wall applied the no-slip condition at the outer boundary of the mesh blocks as well as a zero-velocity condition normal to the boundary.

ROUGHNESS HEIGHT

The roughness height for the structures and topography was set to 0.003 ft, consistent with concrete.

3.5 Model Evaluation

Completed model runs were evaluated quantitatively and qualitatively using velocity magnitude and flow streamlines. The CFD model solves the URANS equations, and data presented at a single time step may contain a maximum or minimum value, which may or may not correspond to the anticipated hydraulic characteristics.

FLUX SURFACES

Flux surfaces were used to monitor the volumetric flow through portions of each CFD model. The surfaces were monitored for mass/volume balance of flow through the model.

MONITORING POINTS

Monitoring points were placed within the model to gather point data for the ladder, powerhouse channel, and tailrace. The monitoring points were selected based on their proximity to key model elements.

4 Results

4.1 Fish Ladder

Three fish ladder simulations were identified in the project scope. Plots showing velocity contours and vectors are presented in plan and profile views. Note the profile views are cut through the center of the inner and outer runs of the fish ladder. Streamlines through the fish ladder and in the immediate downstream region are presented in plan view. An isometric view of the water surface colored by velocity is also presented in the vicinity of the downstream weirs.

4.1.1 Case 1

Normal operation flow through the fish ladder was identified for each of the inlet features: diffuser, ladder, and crest gate. Case 1 assigns 300 cfs over the adjacent crest weir, 60 cfs through the diffuser, and 30 cfs through the fish ladder. The sluice gate is closed for Case 2.

Streamlines colored by velocity are shown on Figure 4-1. Figure 4-2 shows velocity vectors and contours. Figure 4-8 and Figure 4-4 show velocity vector and contour profiles for the inside and outside runs of the fish ladder upstream and downstream of the 180º bend in the fish ladder, respectively. Figure 4-5 shows the water surface colored by velocity in the vicinity of the weirs.

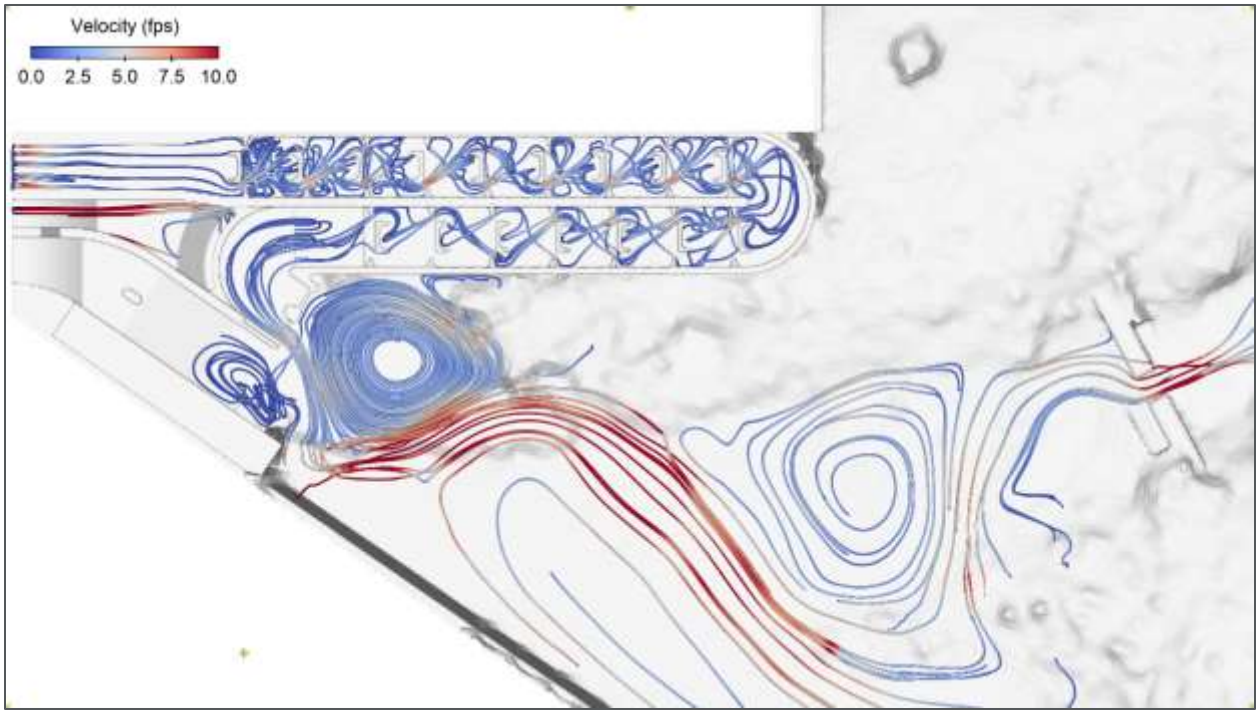

Figure 4-1: Streamlines Colored by Velocity Showing Flow Patterns for Case 1

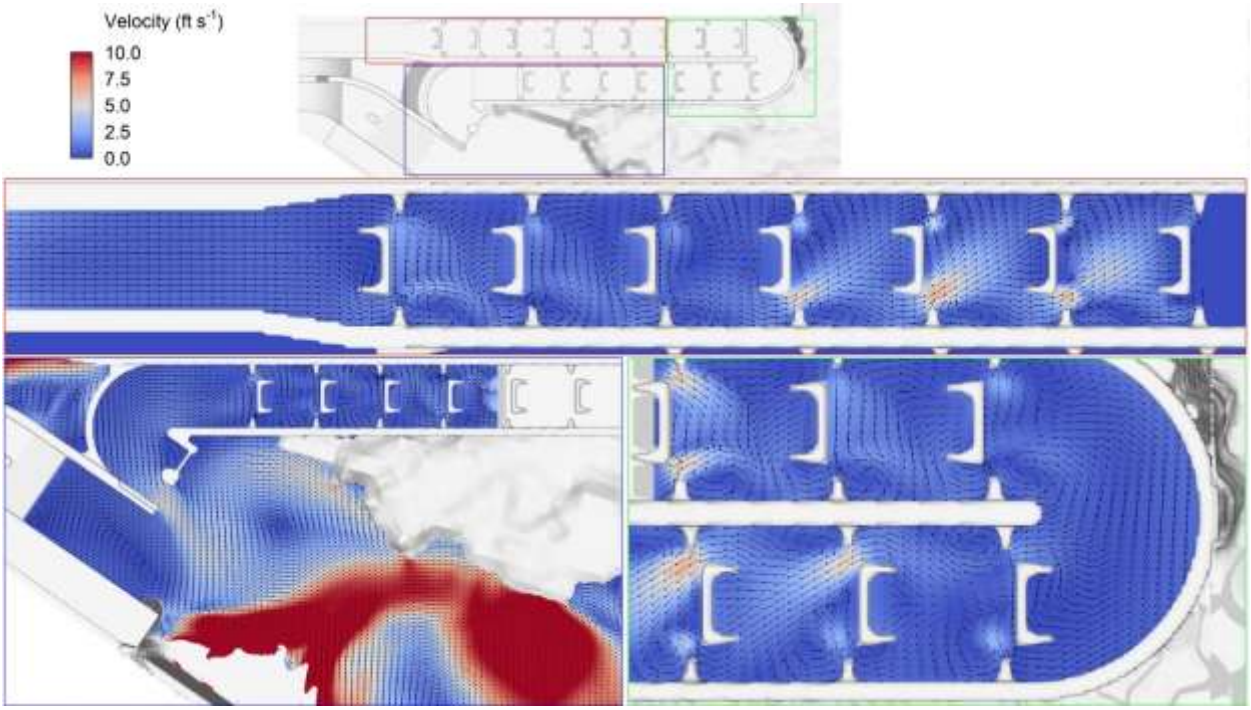

Figure 4-2: Velocity Contours and Vectors for Case 1

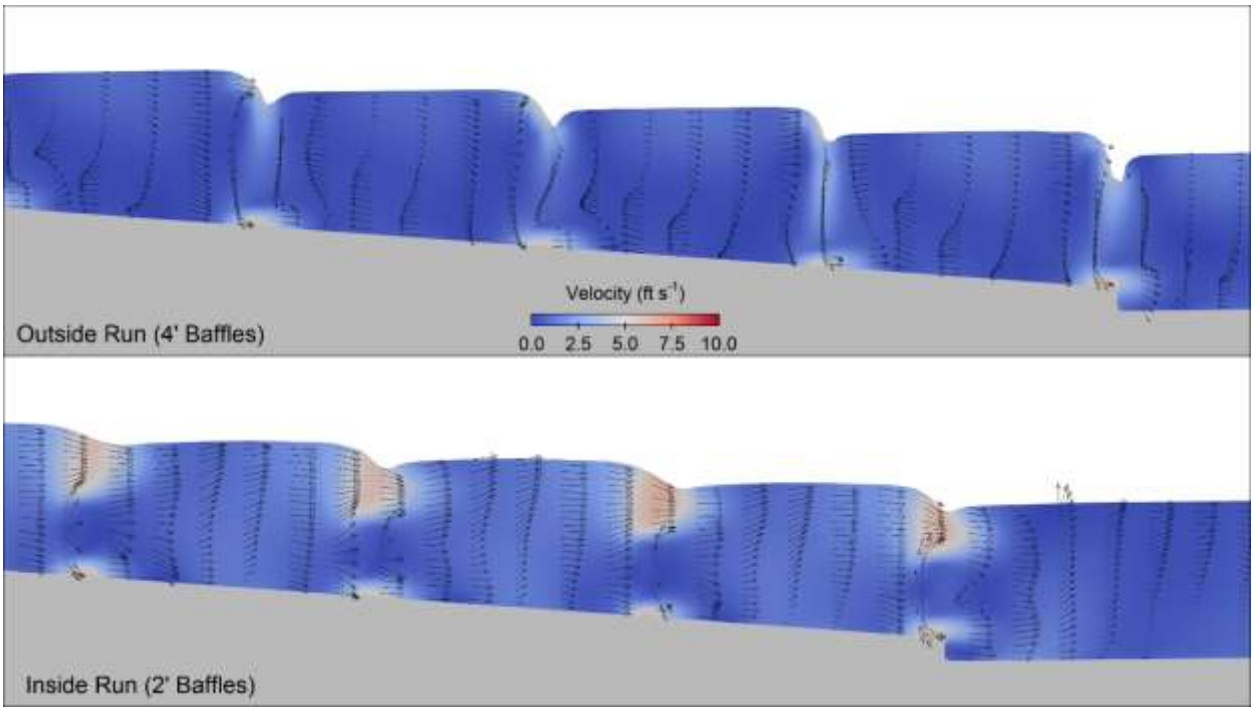

Figure 4-3: Velocity Contour and Vector Profiles Upstream of the 180º Bend

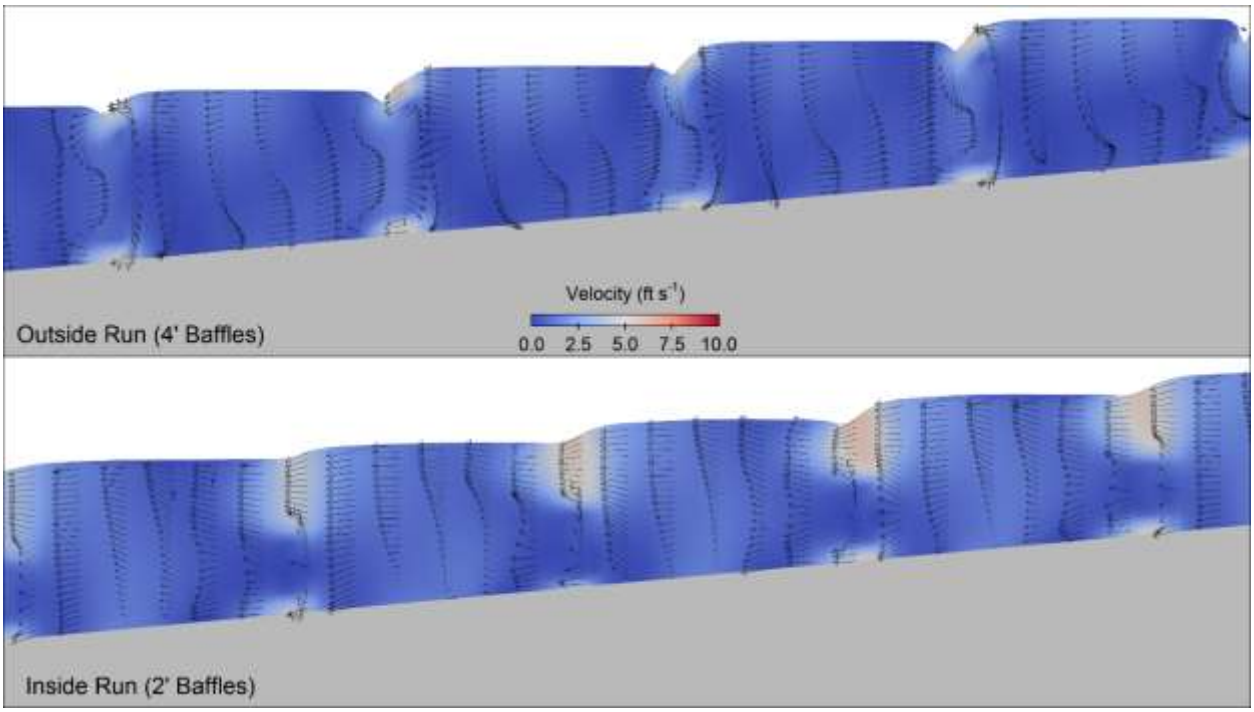

Figure 4-4: Velocity Contour and Vector Profiles Downstream of the 180o Bend

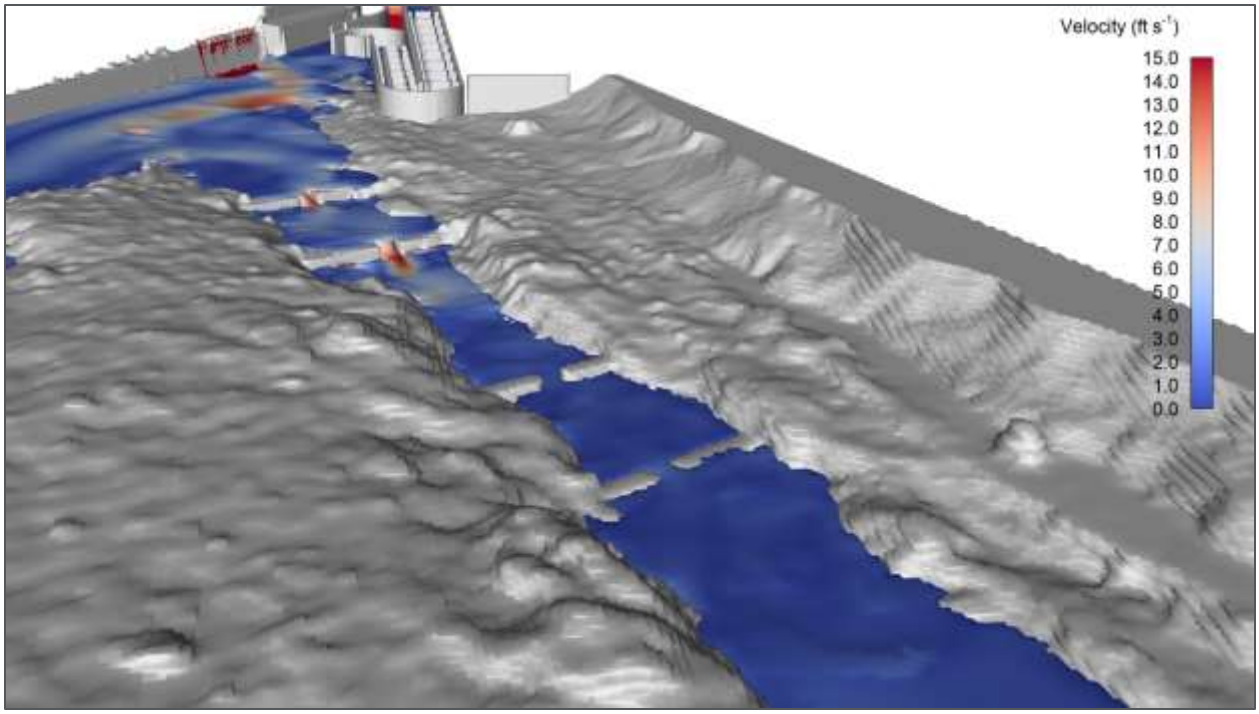

Figure 4-5: Water Surface Colored by Velocity

Flow through the fish ladder showed surface velocities of approximately 6.0 ft per second over the baffles. The vectors and streamlines indicate an area of recirculation on the inside portion of the 180° turn. The depth at the fish ladder entrance was approximately 5.0 to 5.5 ft. Multiple areas of recirculating flow were present downstream of the ladder entrance with a high velocity parallel to the fish ladder entrance. Flow over the bypass weirs does indicate potential surface velocities of about 10.0 ft per second.

4.1.2 Case 2

Normal operation flow through the fish ladder was identified for each of the inlet features: supplemental attraction through the sluice gate, diffuser, and ladder. Case 2 assigns 360 cfs through the sluice gate, 60 cfs through the diffuser, and 30 cfs through the ladder. The crest weir is closed for Case 2.

Streamlines colored by velocity are shown on Figure 4-6. Figure 4-7 shows velocity vectors and contours. Figure 4-8 and Figure 4-9 show velocity vector and contour profiles for the inside and outside runs of the fish ladder upstream and downstream of the 180º bend in the fish ladder, respectively. Figure 4-10 shows the water surface colored by velocity in the vicinity of the weirs.

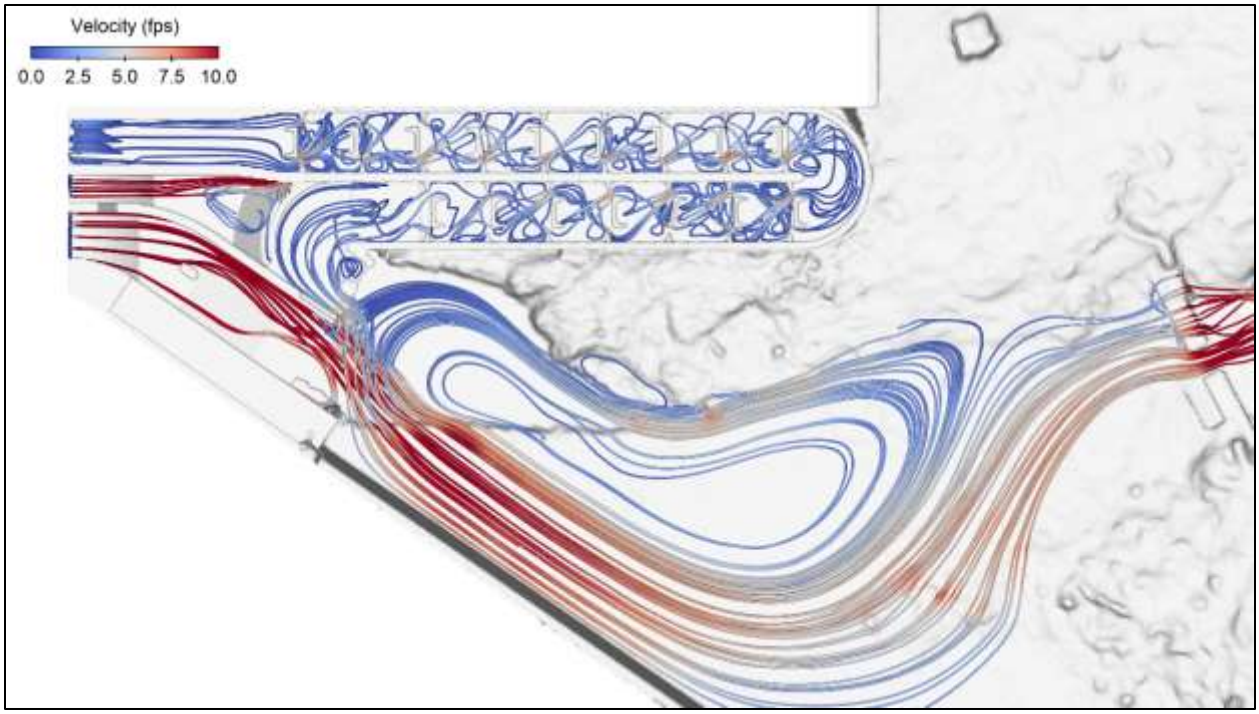

Figure 4-6: Streamlines Colored by Velocity Showing Flow Patterns for Case 2

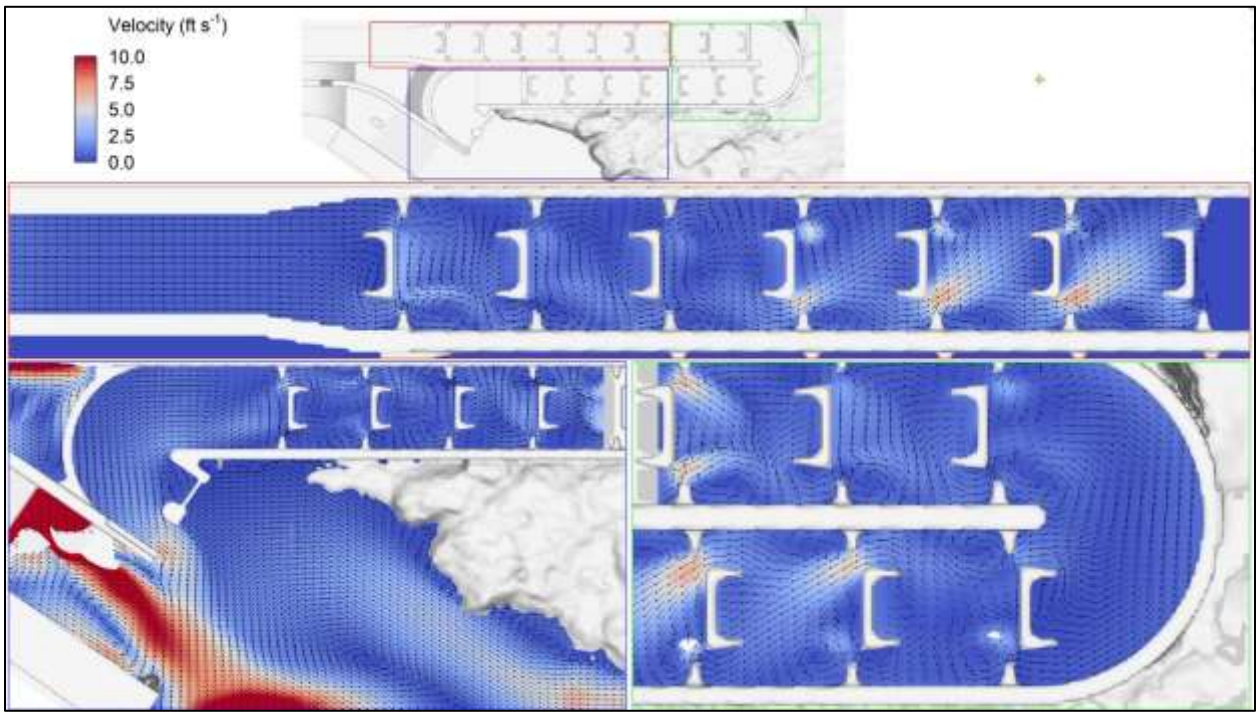

Figure 4-7: Velocity Contours and Vectors for Case 2

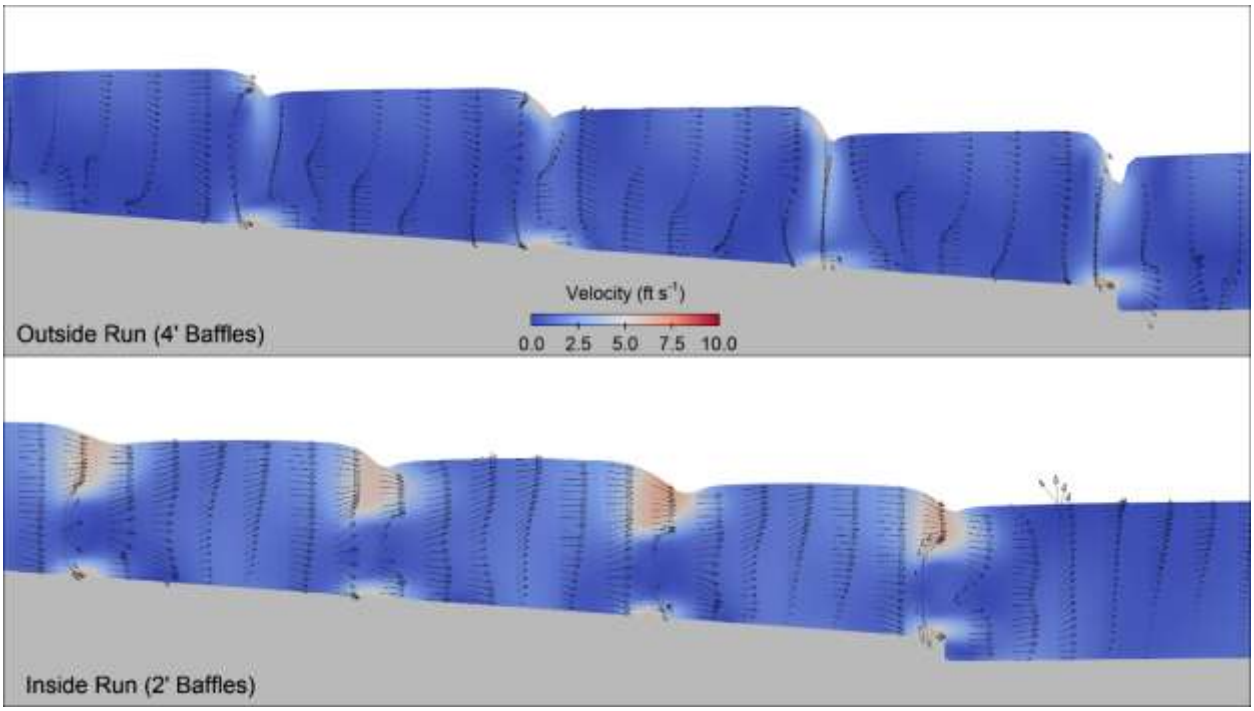

Figure 4-8: Velocity Contour and Vector Profiles Upstream of the 180º Bend

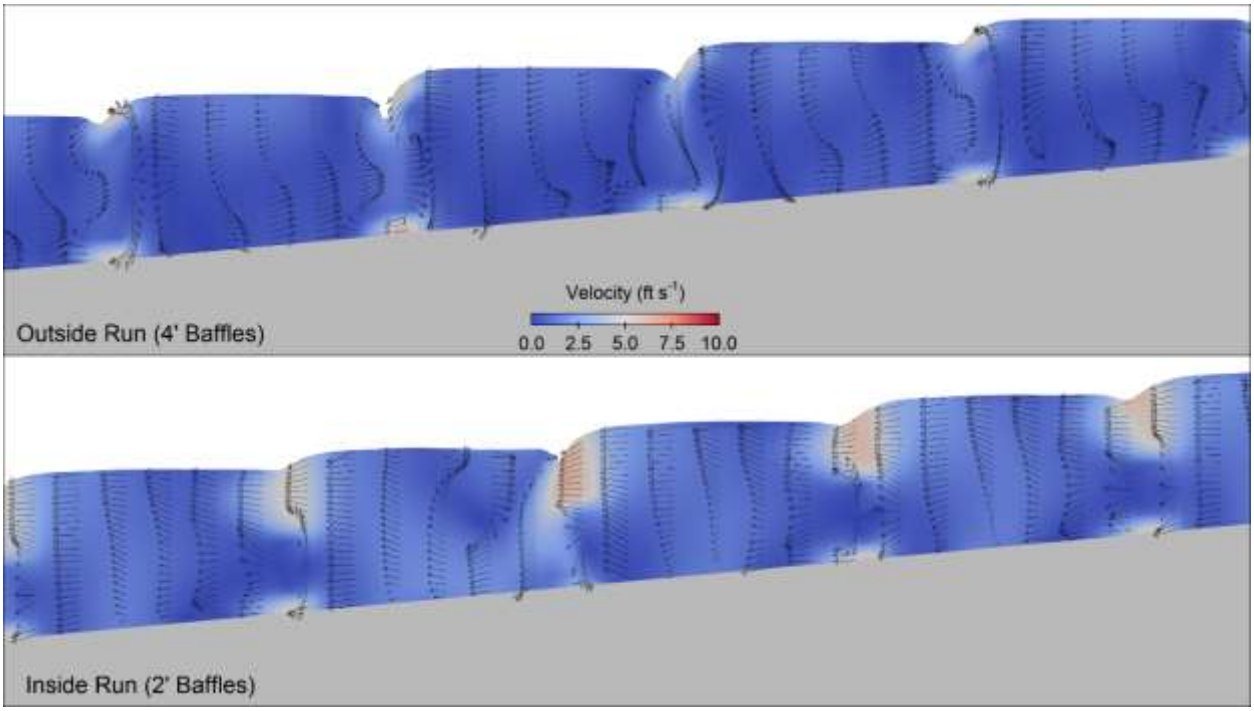

Figure 4-9: Velocity Contour and Vector Profiles Downstream of the 180º Bend

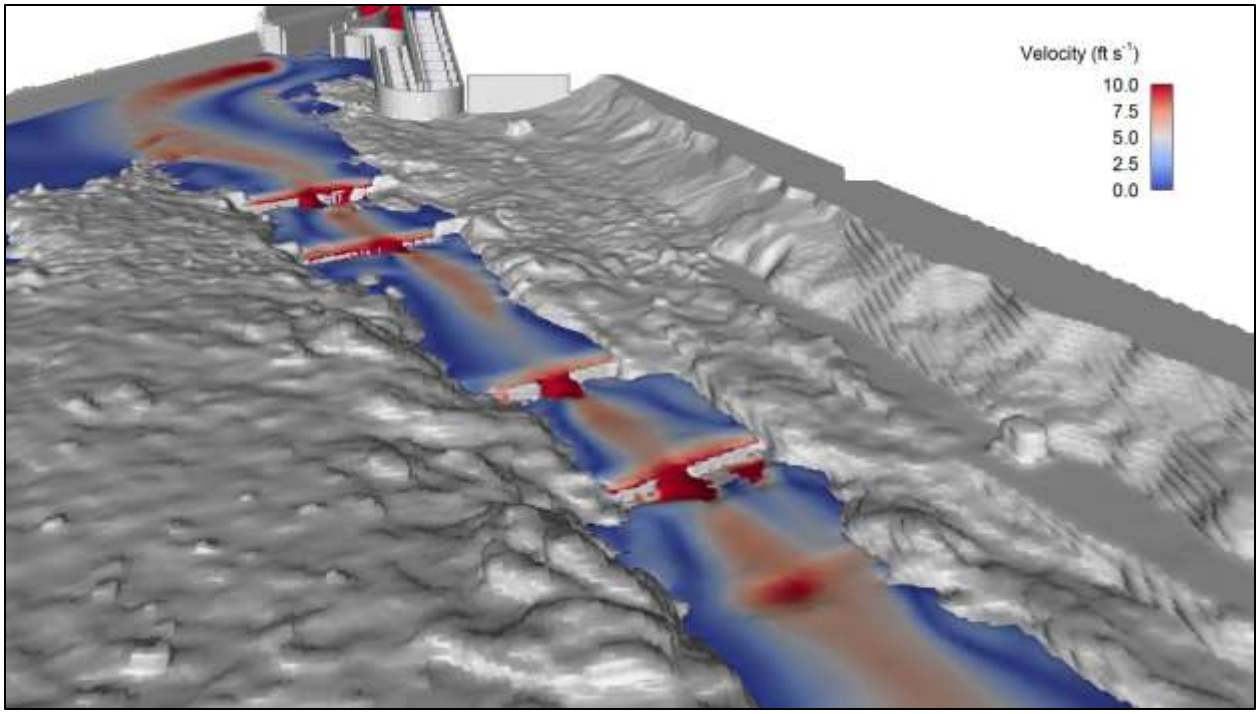

Figure 4-10: Water Surface Colored by Velocity

Flow through the fish ladder showed surface velocities of approximately 6.0 ft per second over the baffles. The vectors and streamlines indicate an area of recirculation on the inside portion of the 180° turn. The depth at the fish ladder entrance was approximately 6.5 ft. Multiple areas of recirculating flow were present downstream of the ladder entrance with a clearly defined flow path from the sluice flow to the first bypass weir. Flow over the bypass weirs does indicate potential surface velocities of about 10.0 ft per second.

4.1.3 Case 3

Case 3 assigns simulates the 5% exceedance flow in the Merrimack River of approximately 26,000 cfs. The powerhouse handles 6,600 cfs, leaving the remaining 19,400 cfs to be passed through the fish ladder and over the spillway crest. The normal operating flow of 30 cfs and 60 cfs were passed through the fish ladder and diffuser gates, respectively. 19,310 cfs is passed equally over the approximately 960 ft spillway crest.

Streamlines colored by velocity are shown on Figure 4-11. Figure 4-12 shows velocity vectors and contours. Figure 4-13 and Figure 4-14 show velocity vector and contour profiles for the inside and outside runs of the fish ladder upstream and downstream of the 180^{o} bend in the fish ladder, respectively. Figure 4-15 shows the water surface colored by velocity in the vicinity of the weirs.

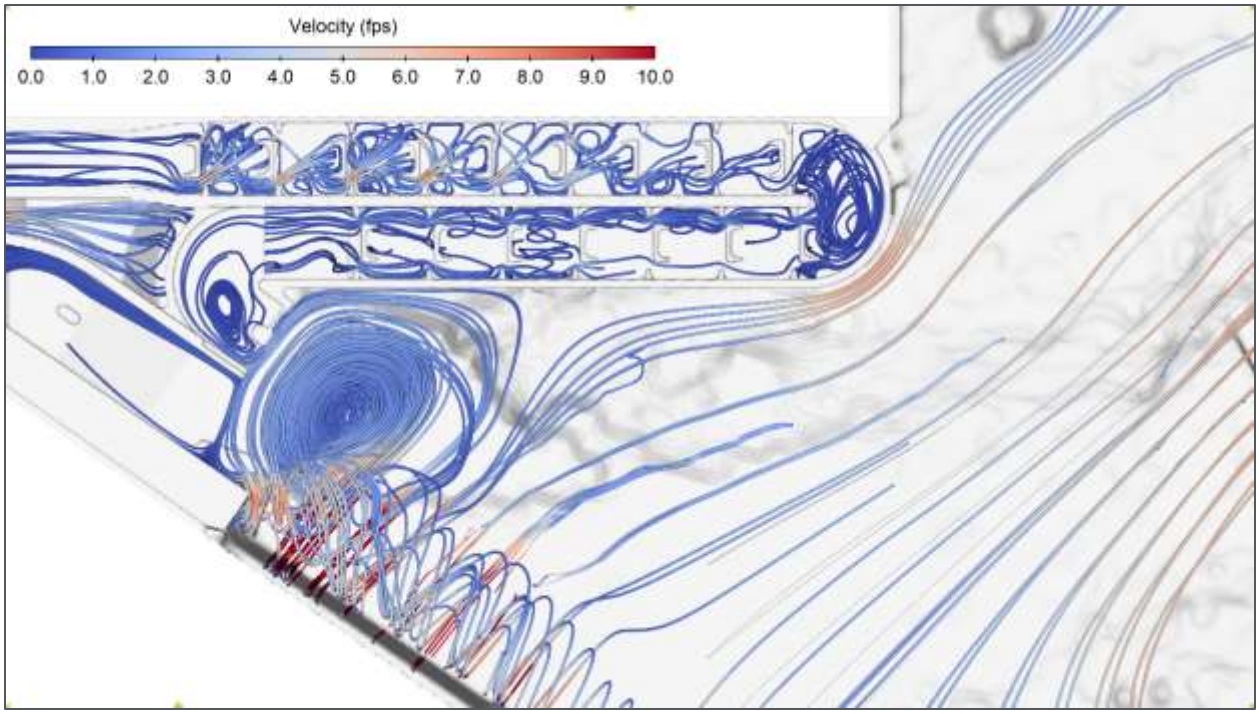

Figure 4-11: Streamlines Colored by Velocity Showing Flow Patterns for Case 3

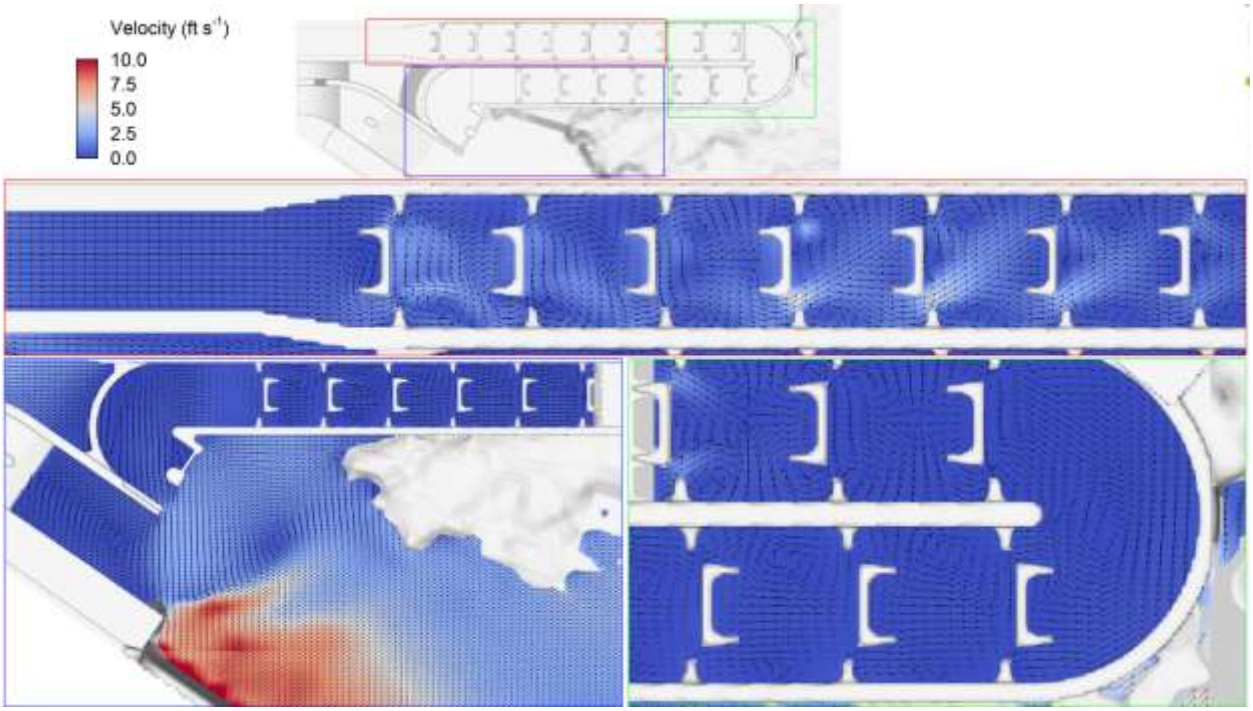

Figure 4-12: Velocity Contours and Vectors for Case 3

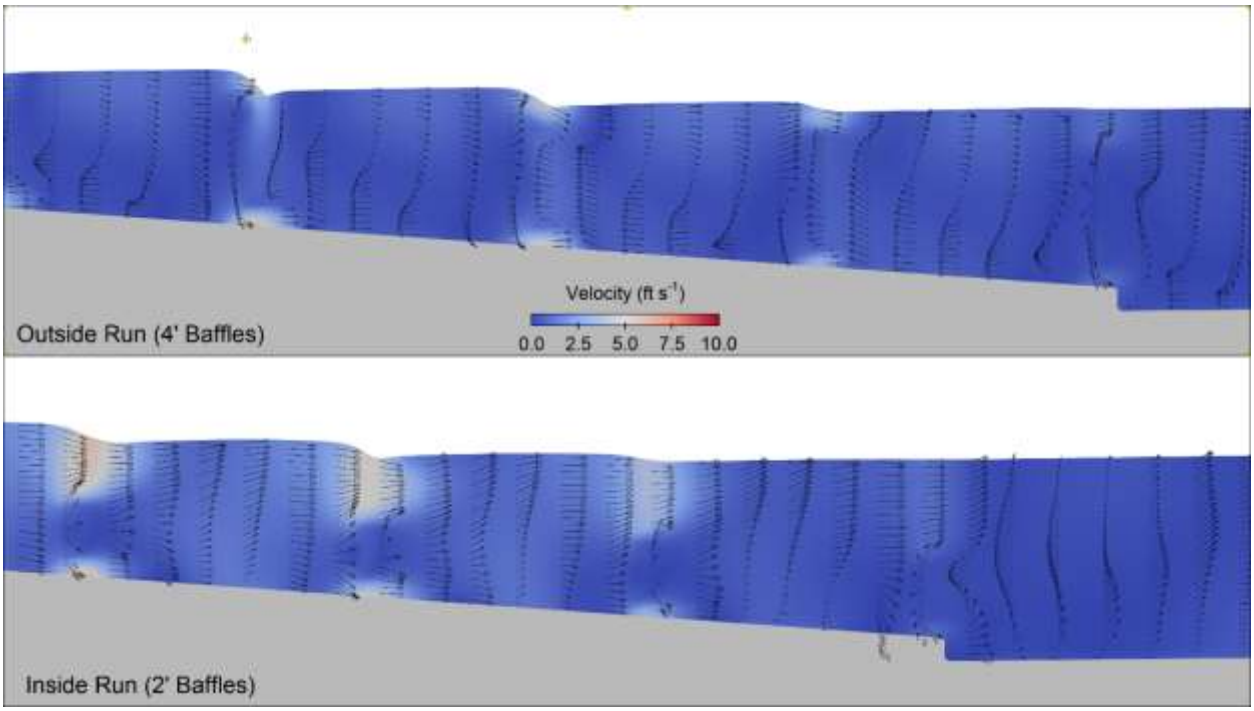

Figure 4-13: Velocity Contour and Vector Profiles Upstream of the 180^{o} Bend

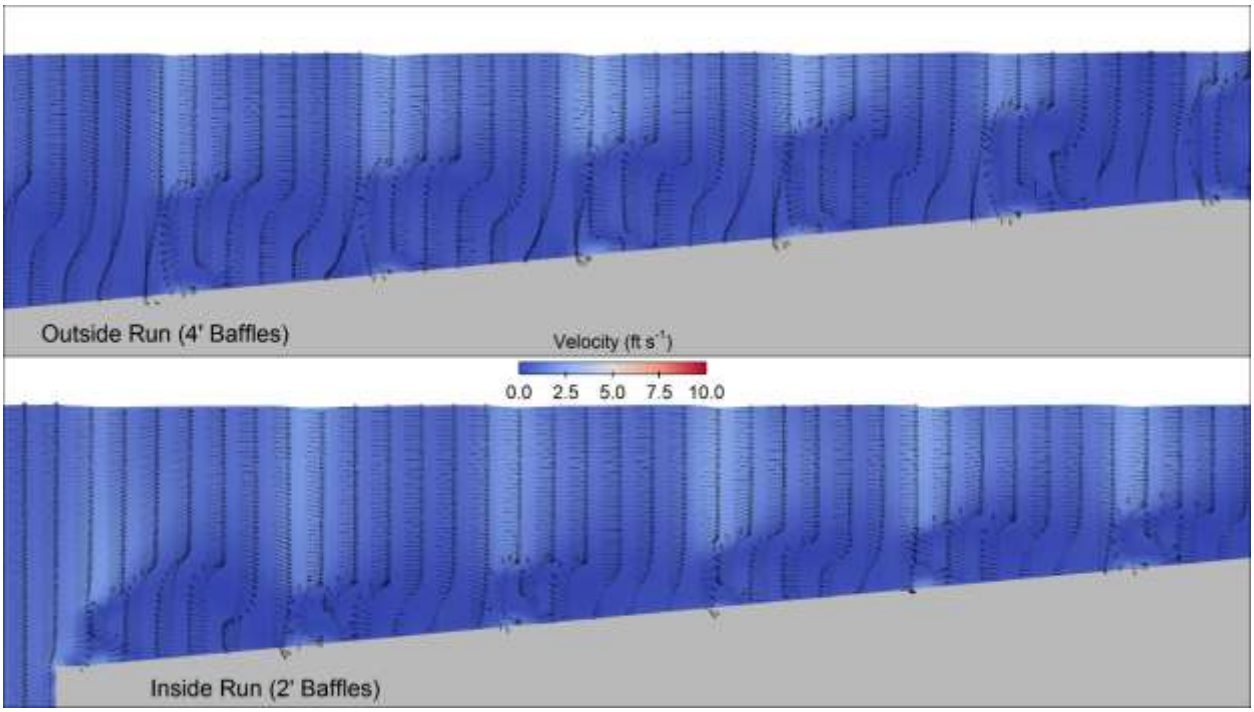

Figure 4-14: Velocity Contour and Vector Profiles Downstream of the 180^{o} Bend

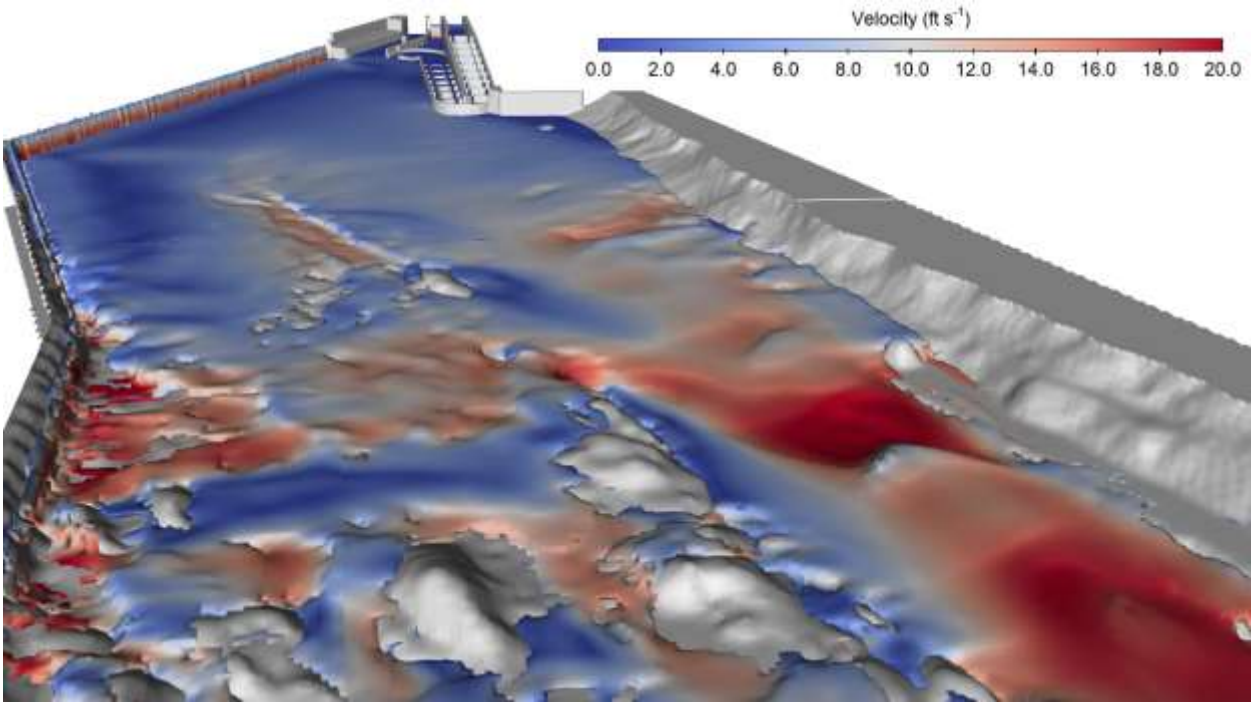

Figure 4-15: Water Surface Colored by Velocity

Flow through the fish ladder showed surface velocities of approximately 6.0 ft per second over the baffles. The vectors and streamlines indicate an area of recirculation on the inside portion of the 180° turn. The depth at the fish ladder entrance was approximately 12.5 ft. Multiple areas of recirculating flow were present downstream of the ladder entrance with a clearly defined flow path from the sluice flow to the first bypass weir. Flow over the bypass weirs does indicate potential surface velocities of about 10.0 ft per second.

4.1.4 Case 4

Case 4 is an update to Case 2 with the fish ladder flow being adjusted to 47 cfs. Case 4 assigns 360 cfs through the sluice gate, 60 cfs through the diffuser, and 47 cfs through the ladder. The crest weir is closed for Case 4.

Streamlines colored by velocity are shown in Figure 4-16 and stream lines colored by source are shown in Figure 4-17. Figure 4-18 shows velocity vectors and contours. Figure 4-19 and Figure 4-20 show velocity vector and contour profiles for the inside and outside runs of the fish ladder upstream and downstream of the 180º bend in the fish ladder, respectively. The water surface profile and depths in the fish ladder are shown in

Figure 4-21. Figure 4-22 shows the water surface colored by velocity in the vicinity of the weirs. The depth and 3ft of depth contour are shown in Figure 4-23. The depth and water surface profile through the bypass weirs is shown in Figure 4-24.

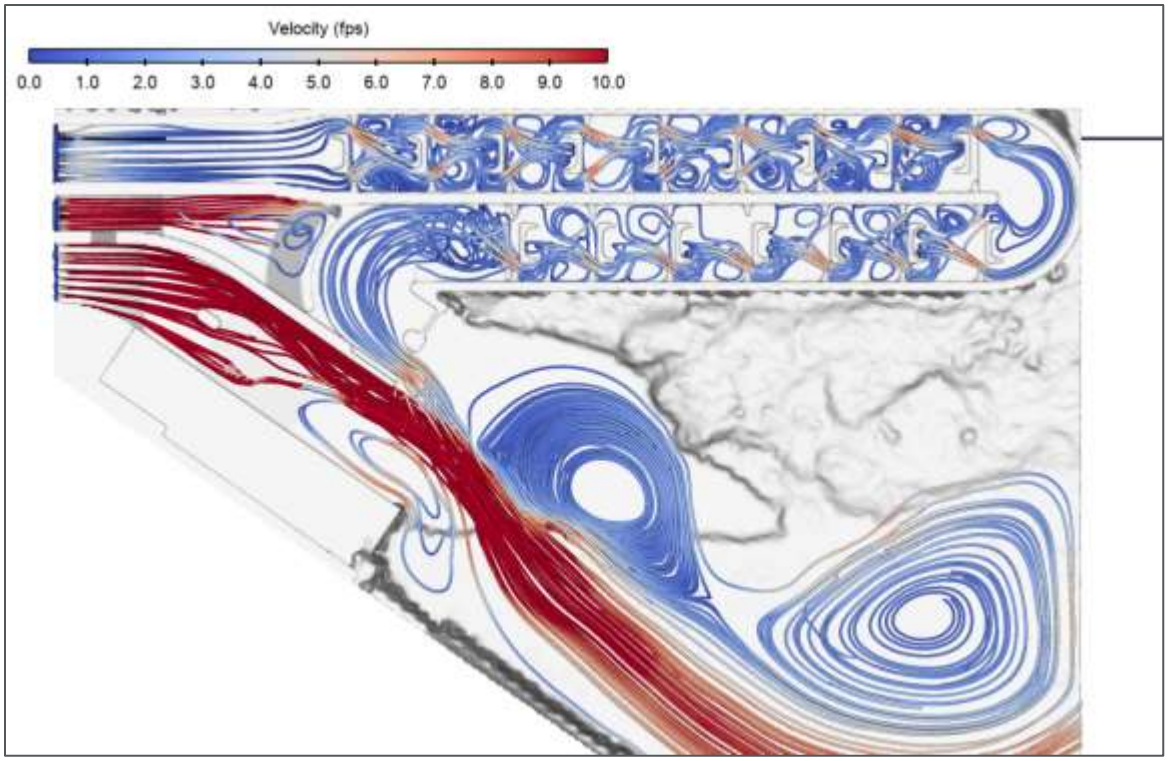

Figure 4-16: Streamlines Colored by Velocity Showing Flow Patterns for Case 4

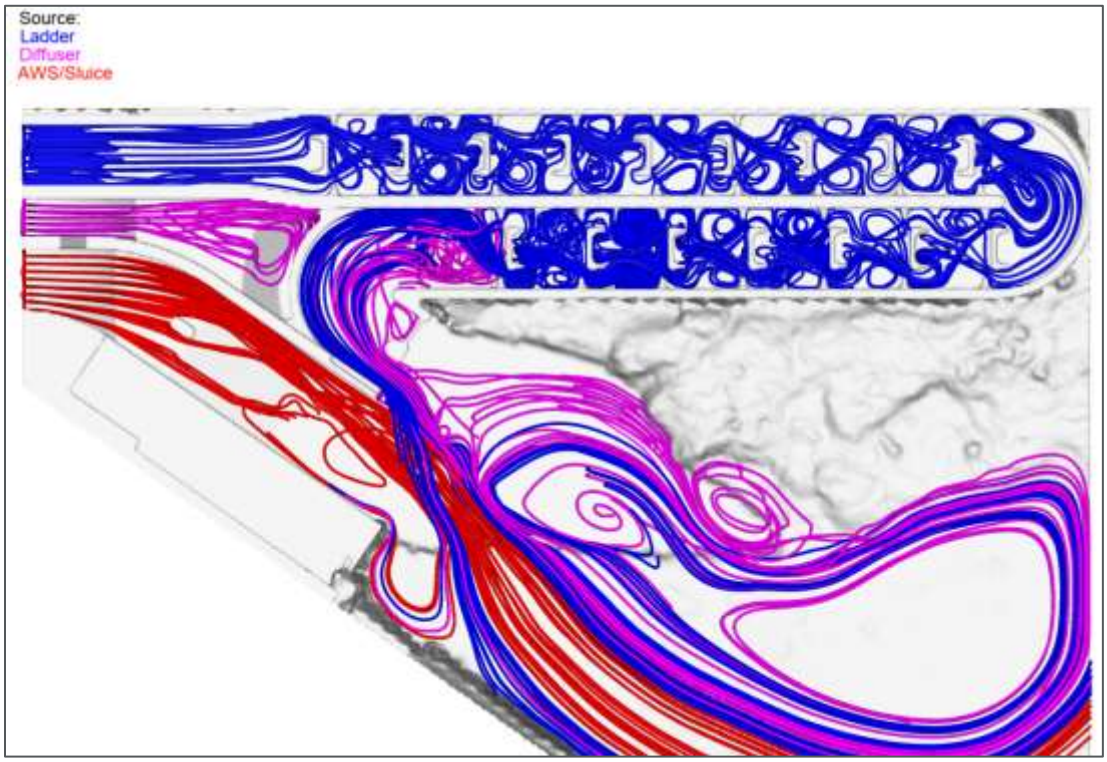

Figure 4-17: Streamlines Colored by Source Showing Flow Patterns for Case 4

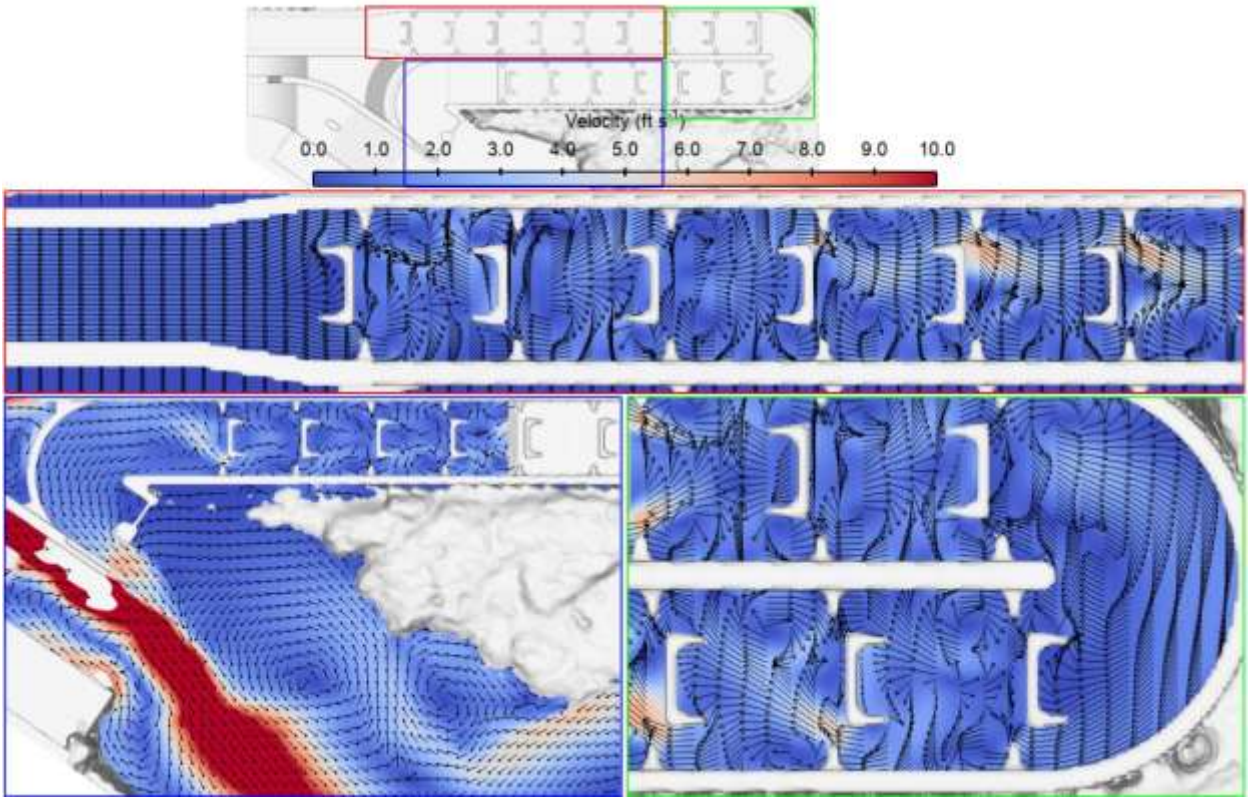

Figure 4-18: Velocity Contours and Vectors for Case 4

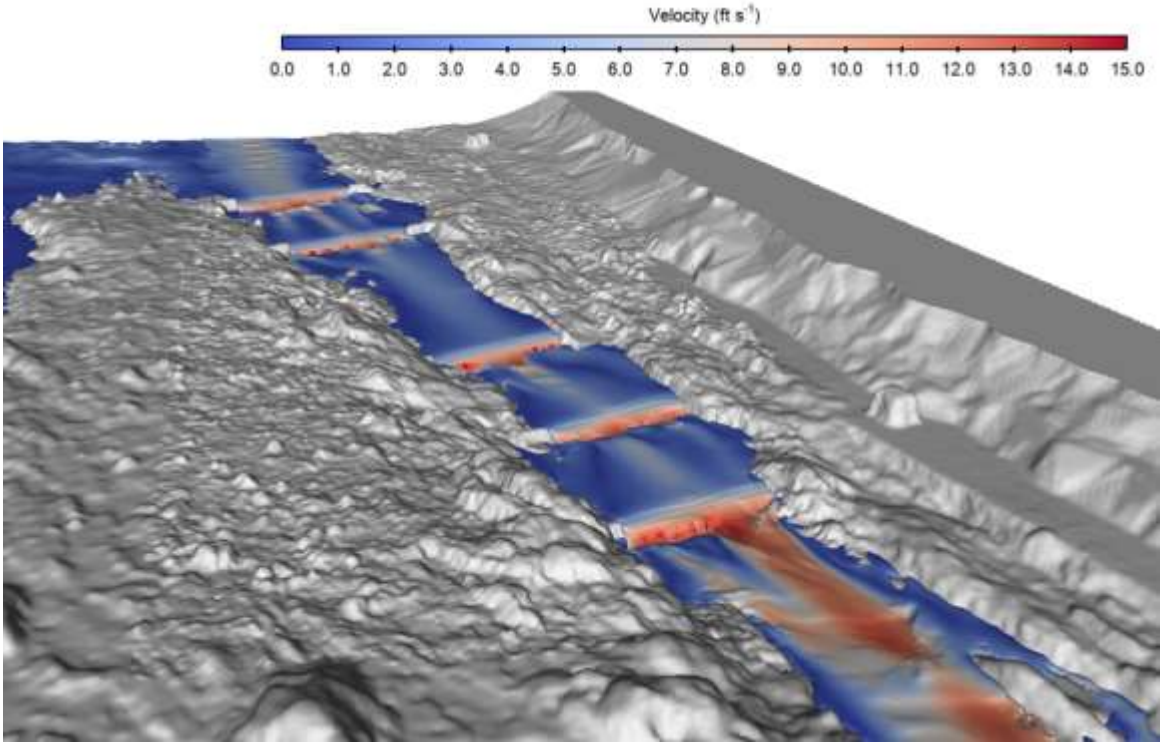

Figure 4-22: Water Surface Colored by Velocity

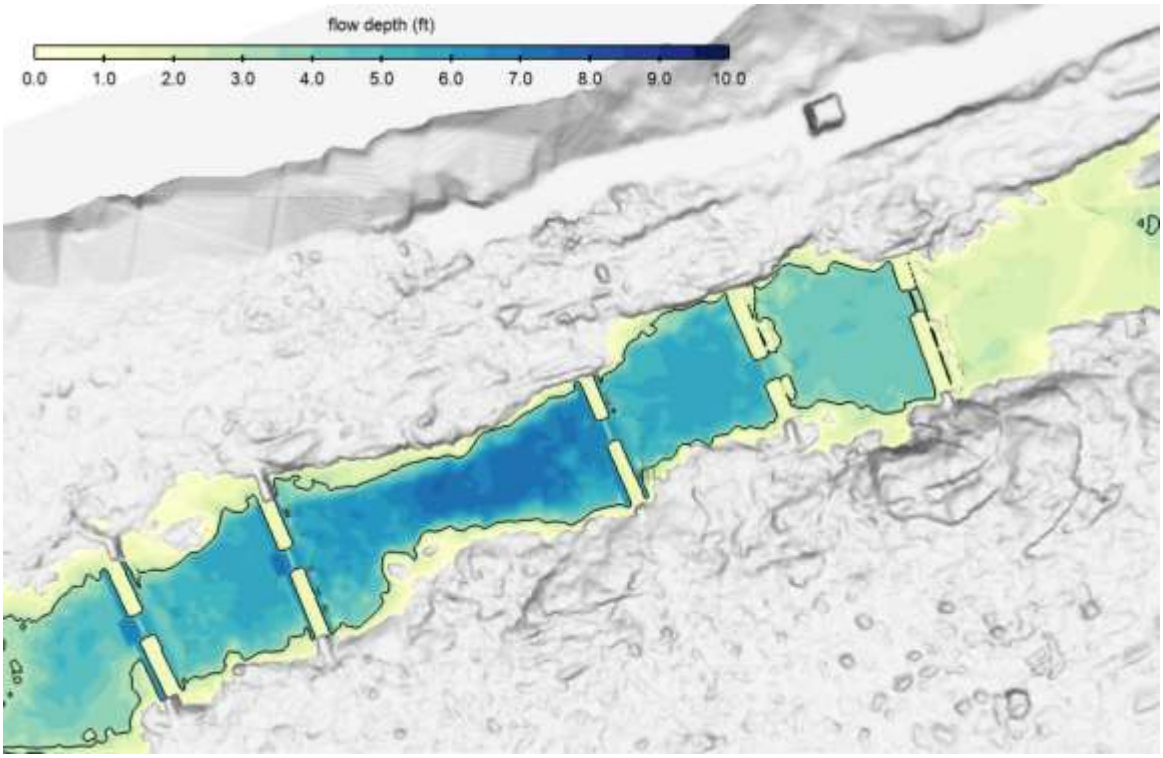

Figure 4-23: Water Depth and 3-foot contour through the Bypass Weirs

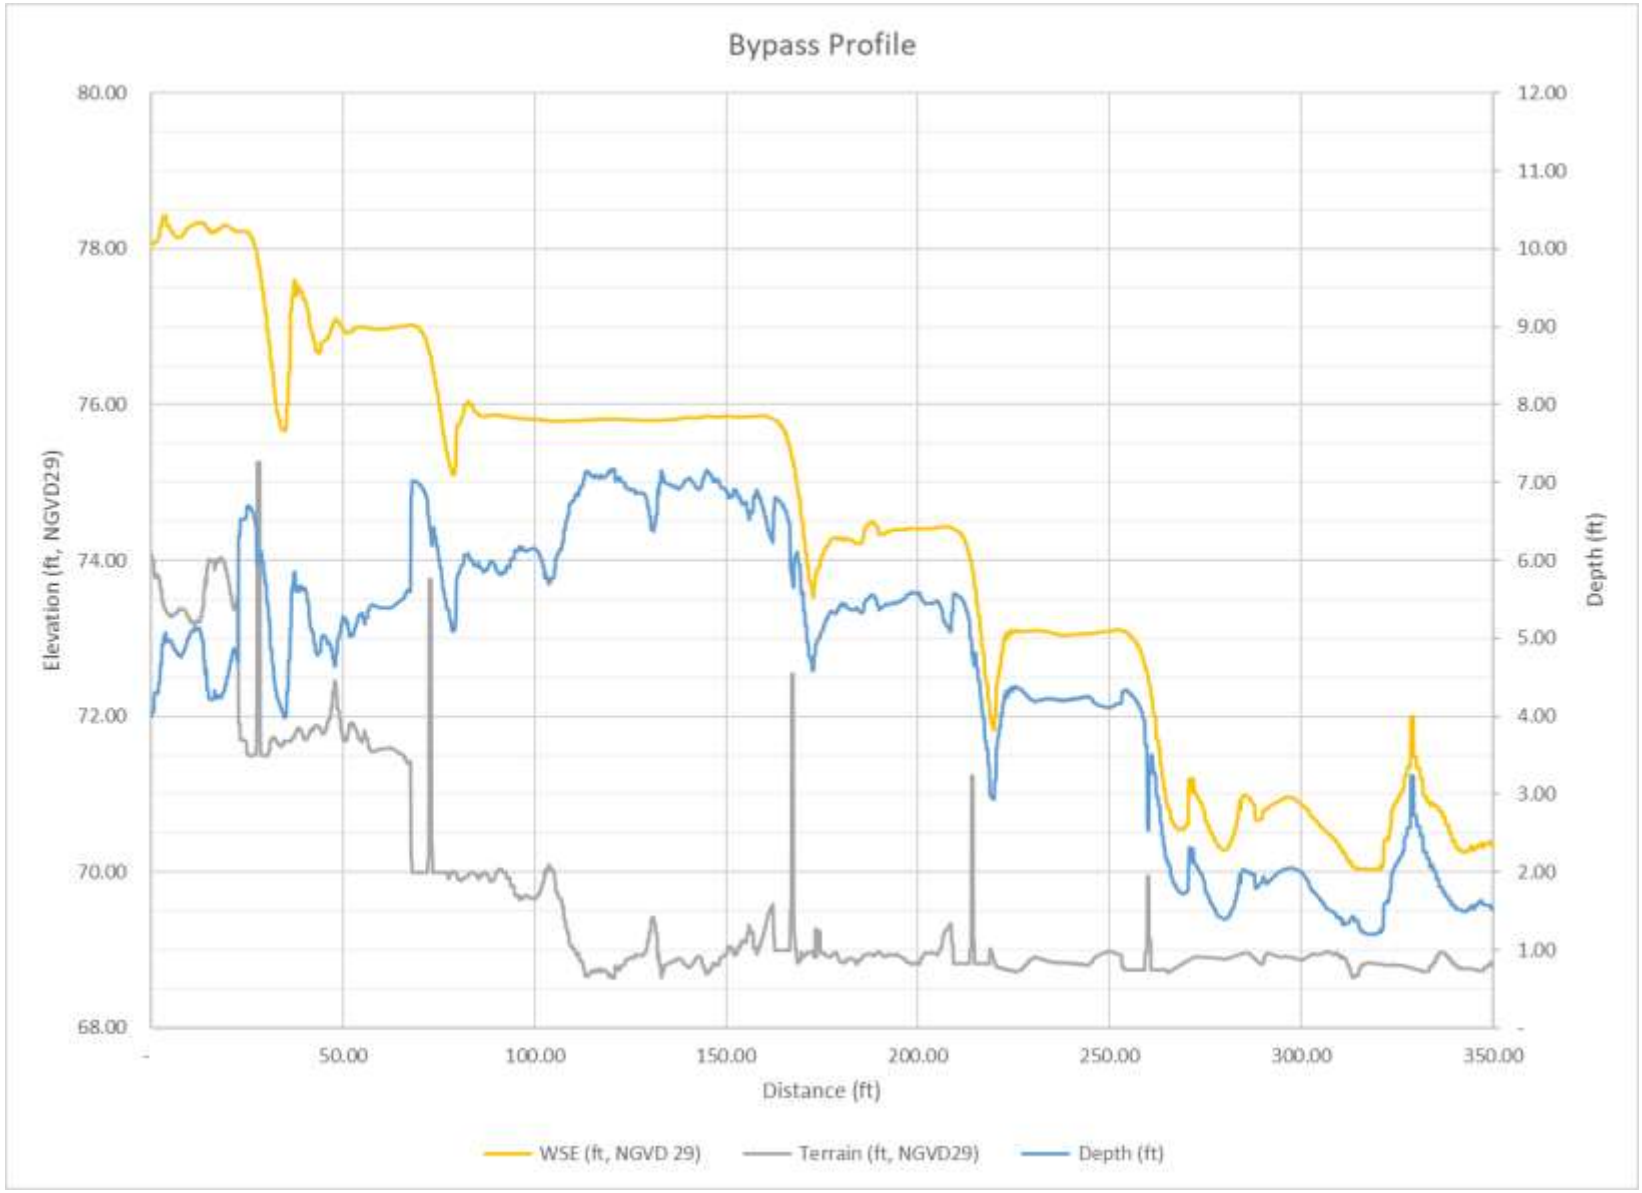

Figure 4-24: Water Surface Profiles and Depths through the Bypass Weirs

Flow through the fish ladder showed surface velocities of approximately 6.0 ft per second over the baffles. The vectors and streamlines indicate an area of recirculation on the inside portion of the 180° turn. The depth at the fish ladder entrance was approximately 5 ft. The water surface profile through the fish ladder showed pool to pool drops of approximately 1 ft with a depth of about 5.5 to 6 ft. Multiple areas of recirculating flow were present downstream of the ladder entrance with a clearly defined flow path from the sluice flow to the first bypass weir. Flow over the bypass weirs does indicate potential surface velocities of about 10.0 to 12.0 ft per second.

4.2 E.L. Field Powerhouse Forebay Model

The three simulations were analyzed and plots showing velocity contours and vectors at multiple depths were exported. The figures depicting streamlines are colored by velocity and model outlet. The red colored streamlines exit the model domain through the AWS and the cyan lines would discharge through the powerhouse.

4.2.1 Case 1 – Full Station Capacity

The 5 percent exceedance model assigns 3,300 cfs through each unit for a total powerhouse flow of 6,600 cfs. The AWS is operating at 130 cfs under this scenario. Figure 4-25 shows the velocity contours and vectors at the water surface (El. 91 ft, NGVD29) and depths of 1 ft (El. 90 ft, NGVD29), 6 ft (El. 85 ft, NGVD29), and 11 ft (El. 85 ft, NGVD29). The streamlines colored by velocity are shown on Figure 4-26. Figure 4-27 shows streamlines colored by model outlet. Figure 4-28 through Figure 4-33 show velocity contour or vectors on multiple sections in the forebay.

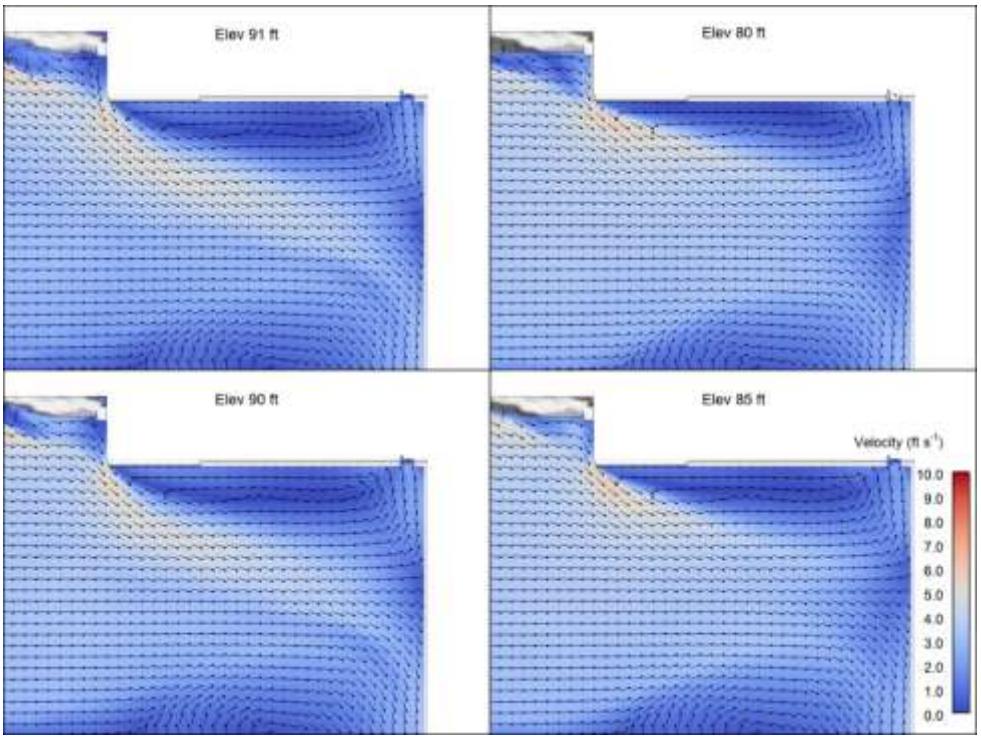

Figure 4-25: Velocity Contours and Vectors for Case 1

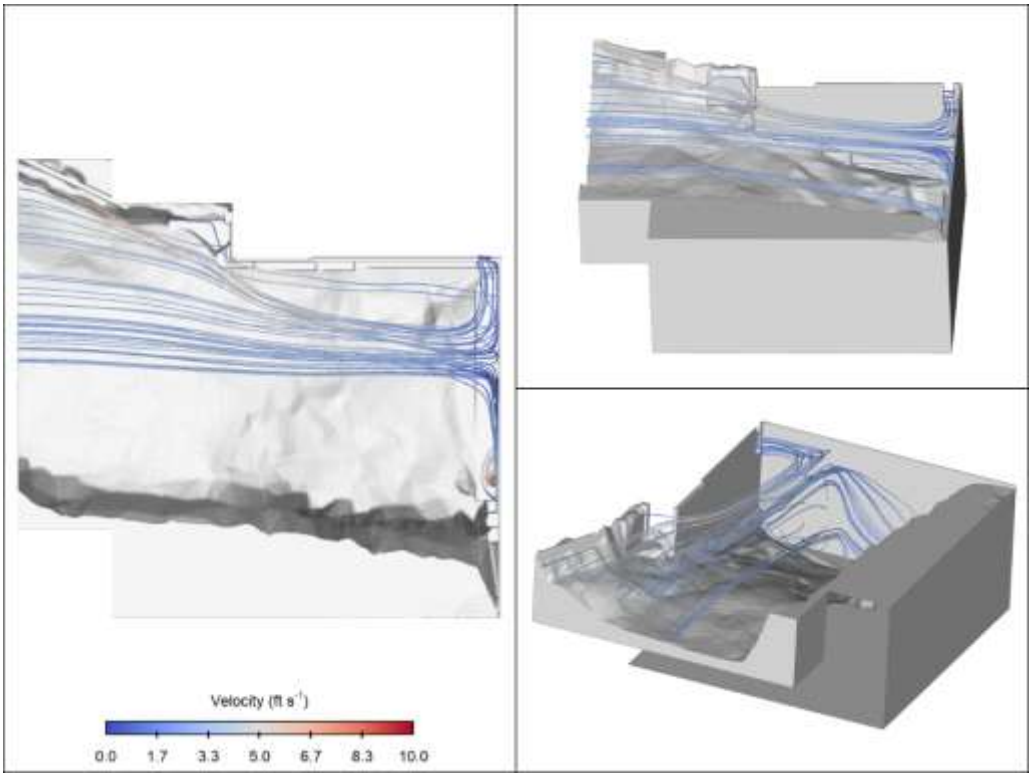

Figure 4-26: Streamlines Colored by Velocity Showing Flow Patterns

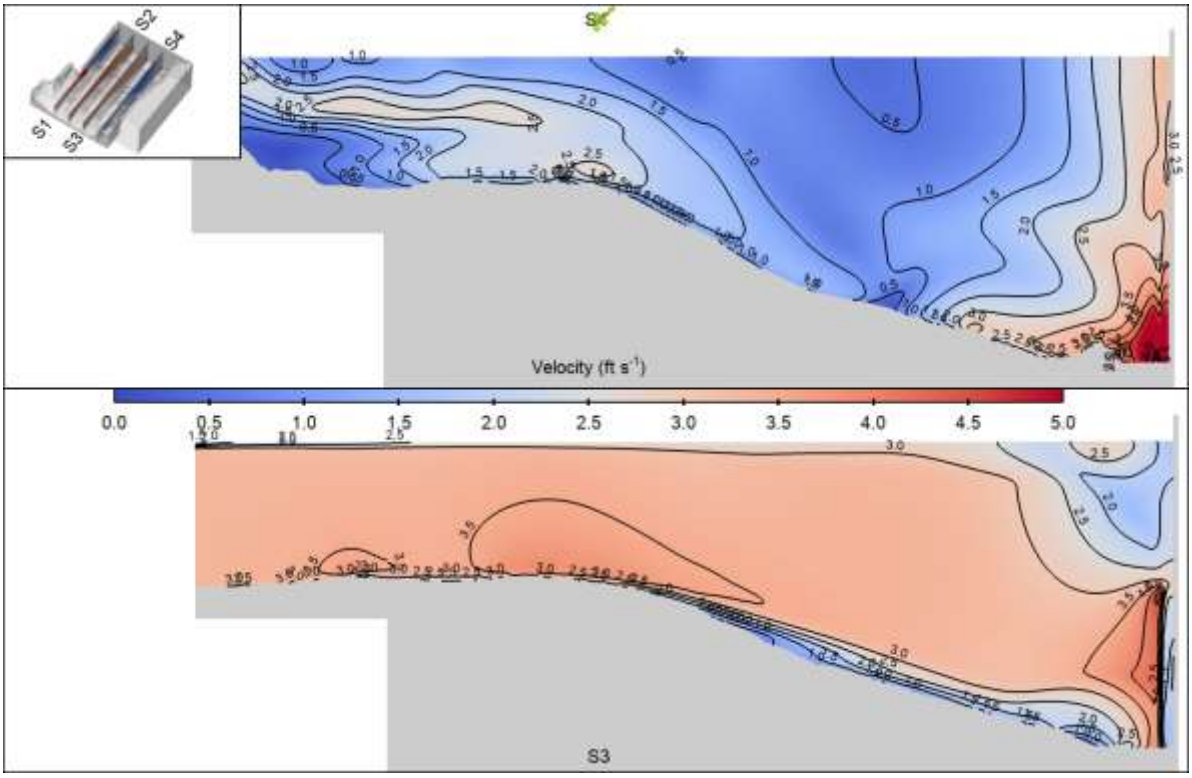

Figure 4-31: Velocity Contours on Sections for Case 1

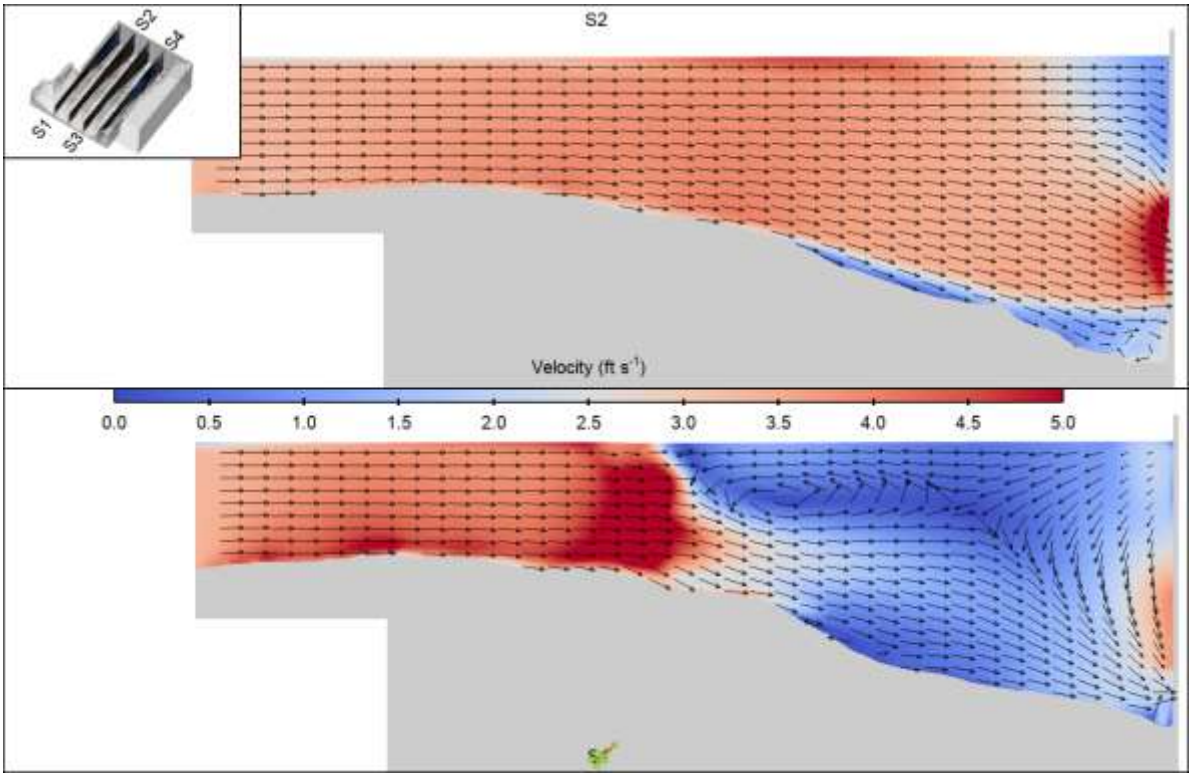

Figure 4-32: Velocity Vectors on Sections for Case 1

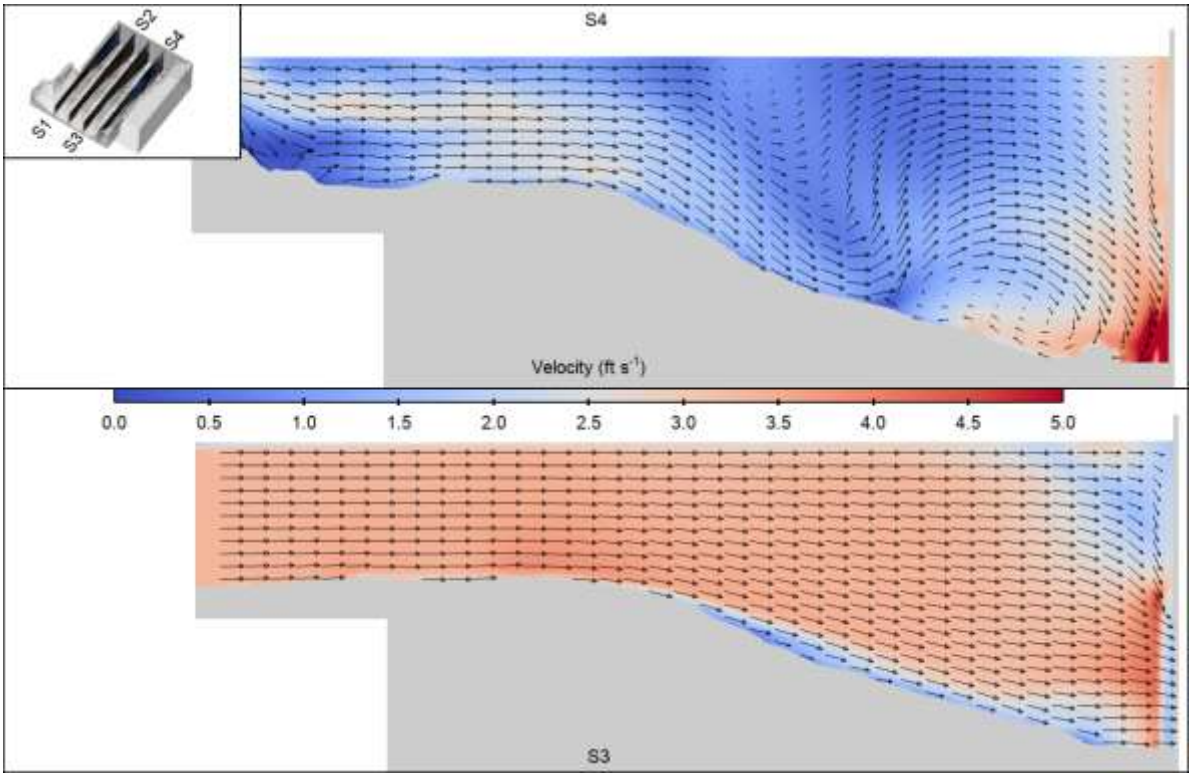

Figure 4-33: Velocity Vectors on Sections for Case 1

The velocity patterns show a large recirculation area along the fishway structure. Flow approaches the fishway entrance parallel to the powerhouse structure. The streamlines indicate flow entering the fishway originates from the left bank (viewing downstream) of the powerhouse channel.

4.2.2 Case 2 – 75% Exceedance

The 75 percent exceedance model assigns 1,310 cfs through each unit for a total powerhouse flow of 2,620 cfs. The AWS is operating at 130 cfs under this scenario. Figure 4-34 shows the velocity contours and vectors at the water surface (El. 91 ft, NGVD29) and depths of 1 ft (El. 90 ft, NGVD29), 6 ft (El. 85 ft, NGVD29), and 11 ft (El. 85 ft, NGVD29). The streamlines colored by velocity are shown on Figure 4-35. Figure 4-36 shows streamlines colored by model outlet. Figure 4-37 through Figure 4-42 show velocity contour or vectors on multiple sections in the forebay.

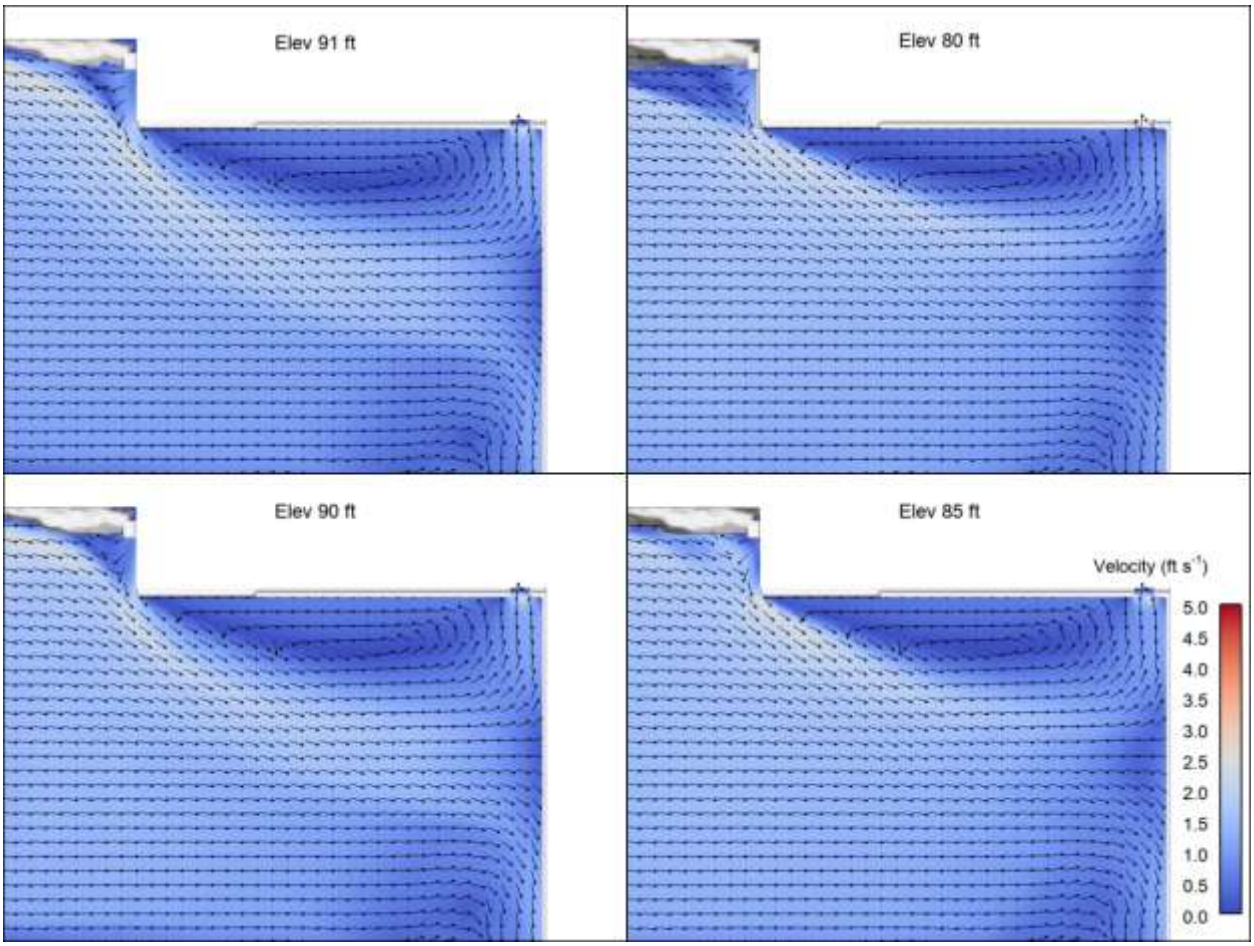

Figure 4-34: Velocity Contours and Vectors for Case 2

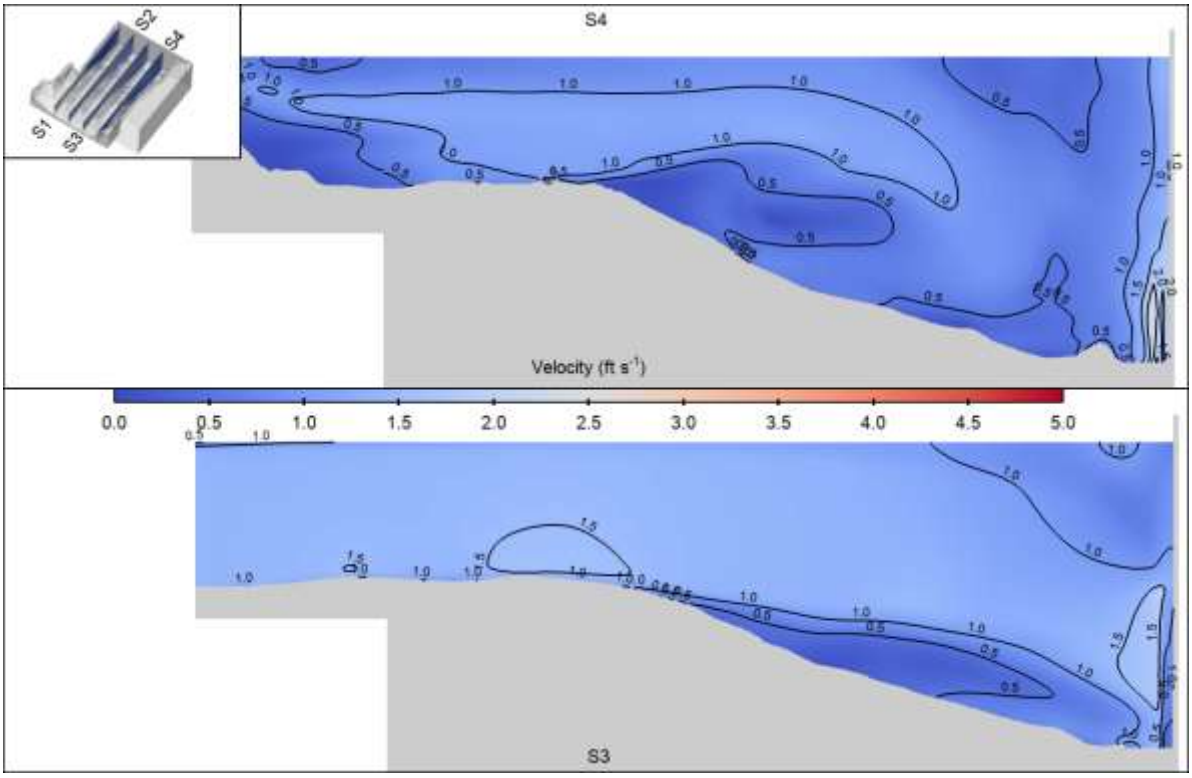

Figure 4-40: Velocity Contours on Sections for Case 2

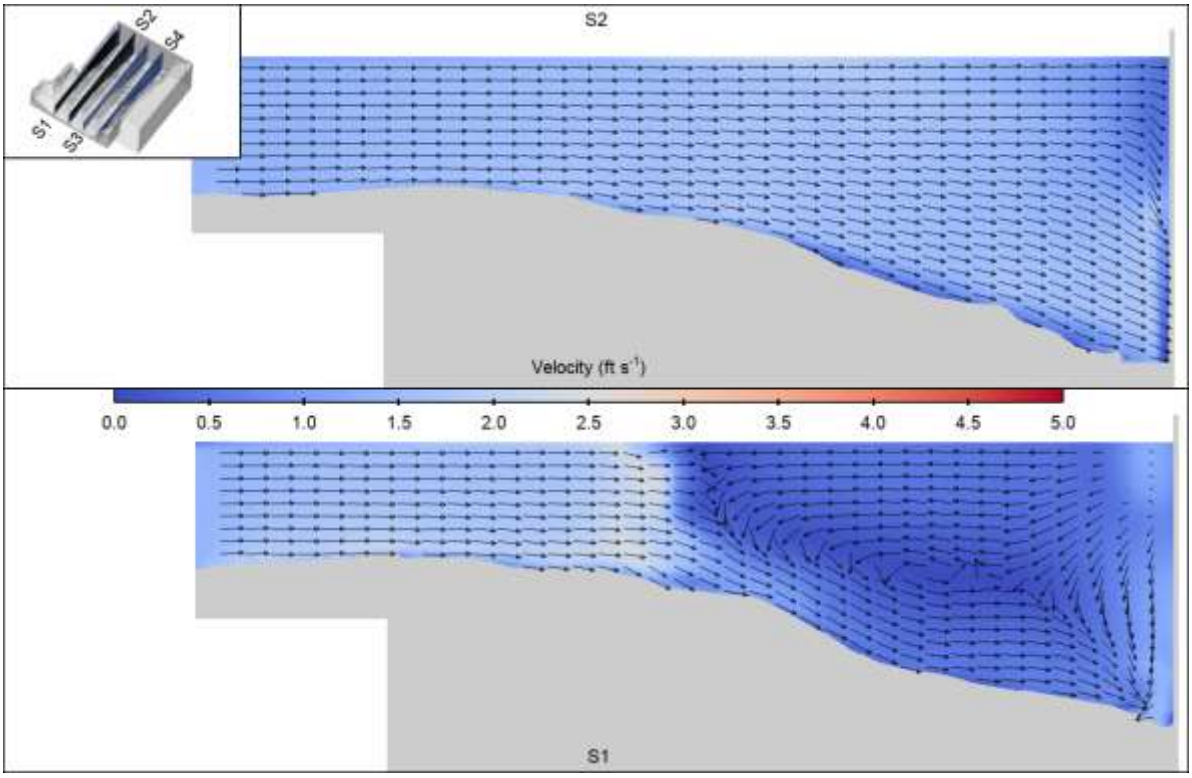

Figure 4-41: Velocity Vectors on Sections for Case 2

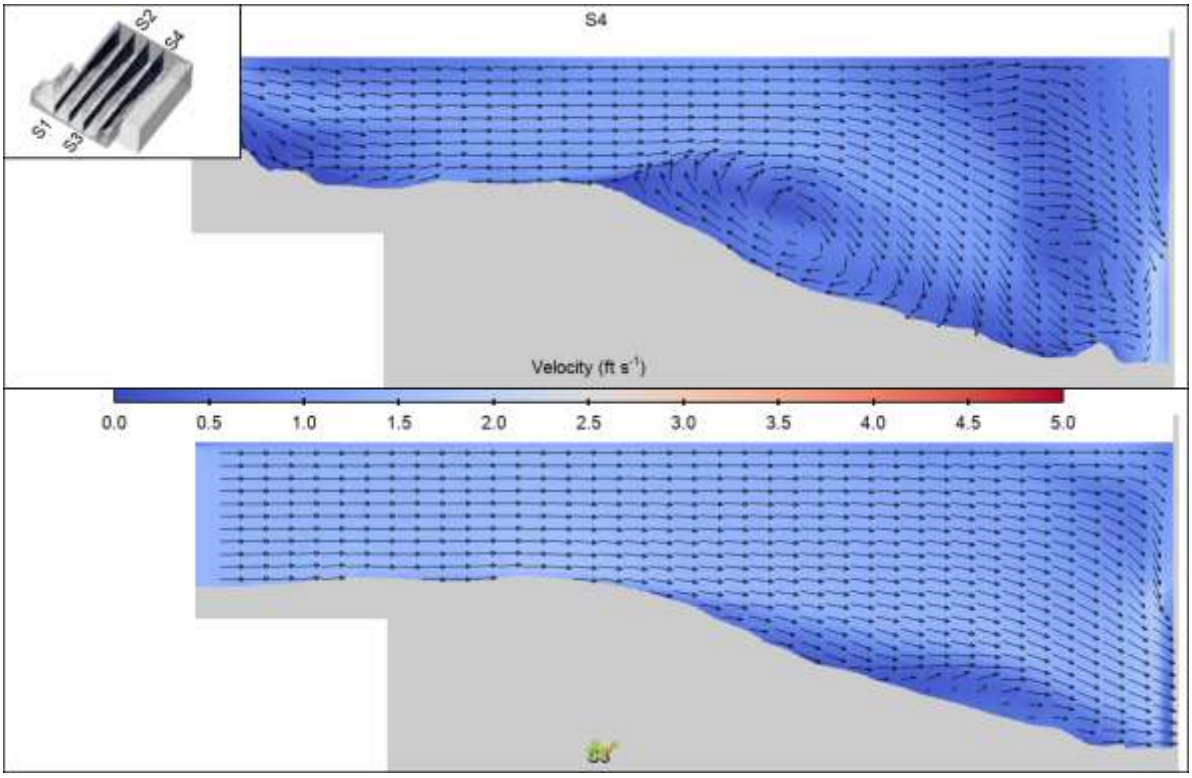

Figure 4-42: Velocity Vectors on Sections for Case 2

Similar to Case 1, The velocity patterns show a large recirculation area along the fishway structure. Flow approaches the fishway entrance parallel to the powerhouse structure. The streamlines indicate that flow entering the fishway originates from the left bank (viewing downstream) of the powerhouse channel.

4.2.3 Case 3 – Minimum Unit Flow

The 75 percent exceedance model assigns 600 cfs through each unit for a total powerhouse flow of 1,200 cfs. The AWS is operating at 130 cfs under this scenario. Figure 4-43 shows the velocity contours and vectors at the water surface (El. 91 ft, NGVD29) and depths of 1 ft (El. 90 ft, NGVD29), 6 ft (El. 85 ft, NGVD29), and 11 ft (El. 85 ft, NGVD29). The streamlines colored by velocity are shown on Figure 4-44. Figure 4-45 shows streamlines colored by model outlet. Figure 4-46 through Figure 4-51 show velocity contour or vectors on multiple sections in the forebay.

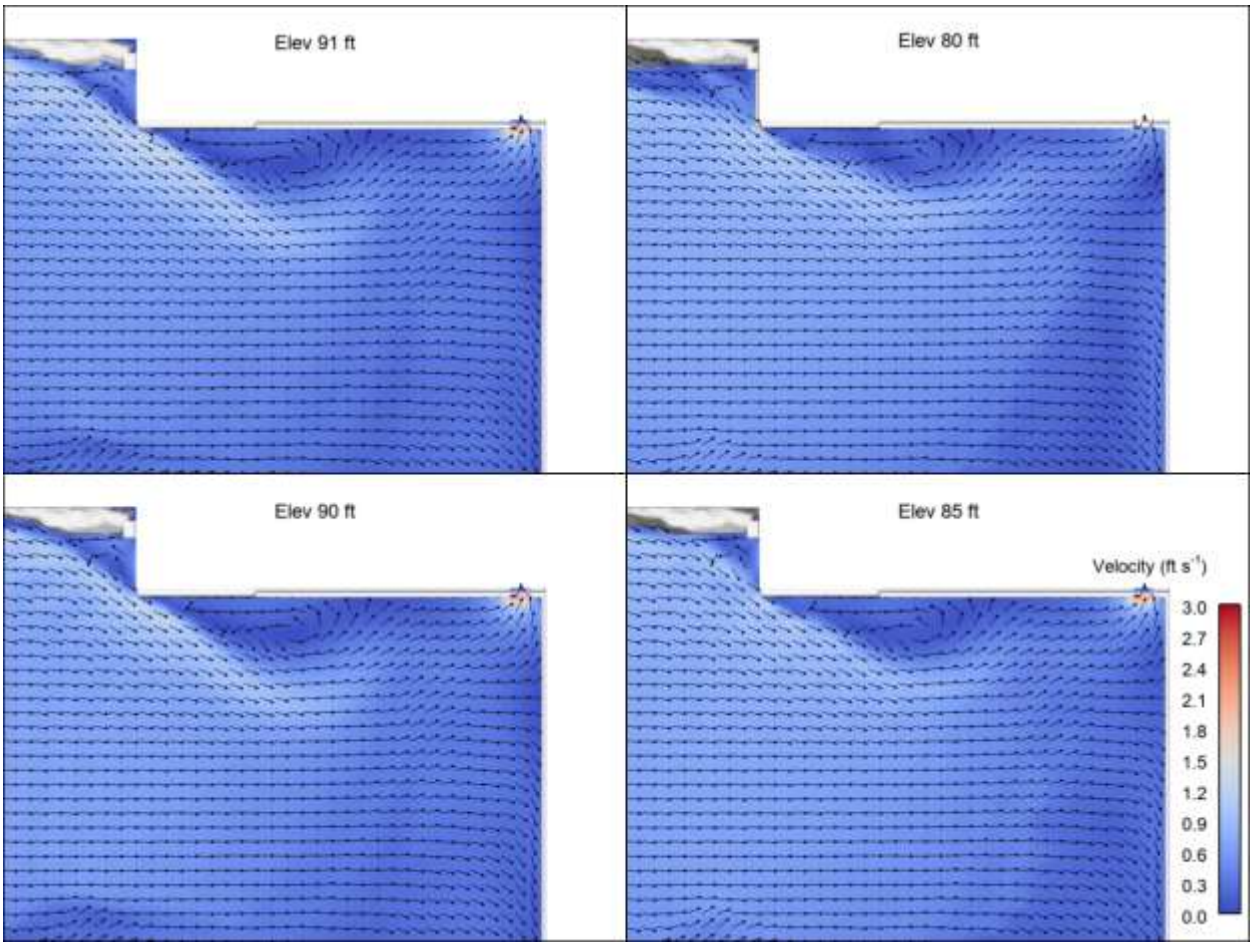

Figure 4-43: Velocity Contours and Vectors for Case 3

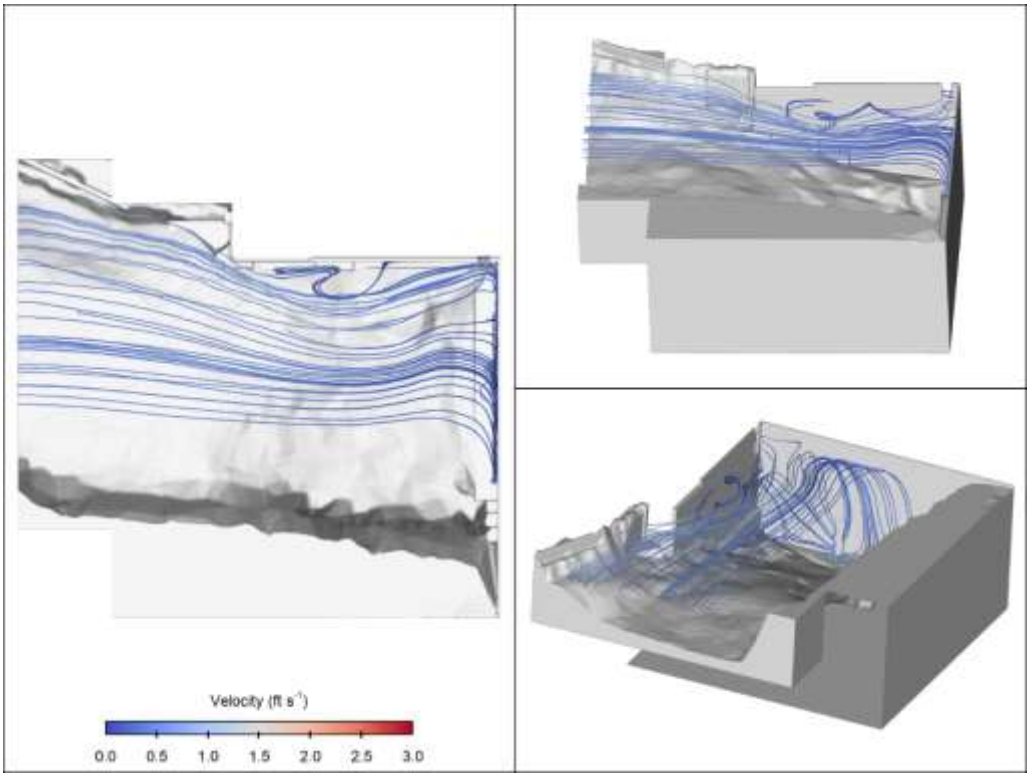

Figure 4-44: Streamlines Colored by Velocity Showing Flow Patterns for Case 3

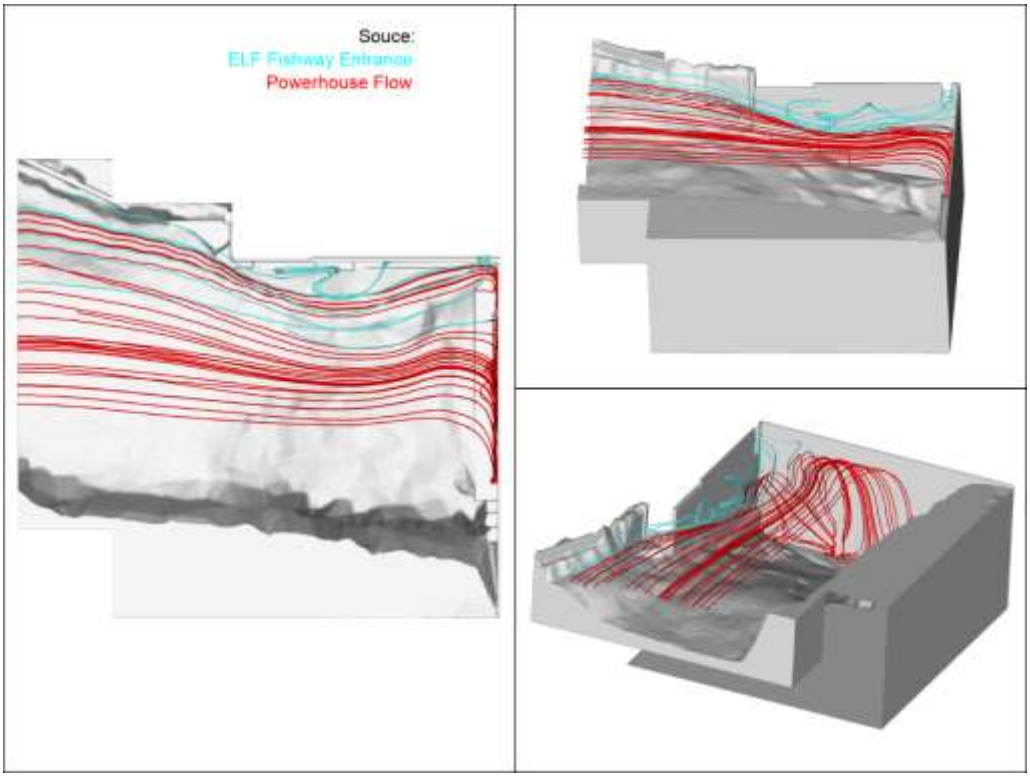

Figure 4-45: Streamlines Colored by Model Outlet Showing Flow Patterns for Case 3

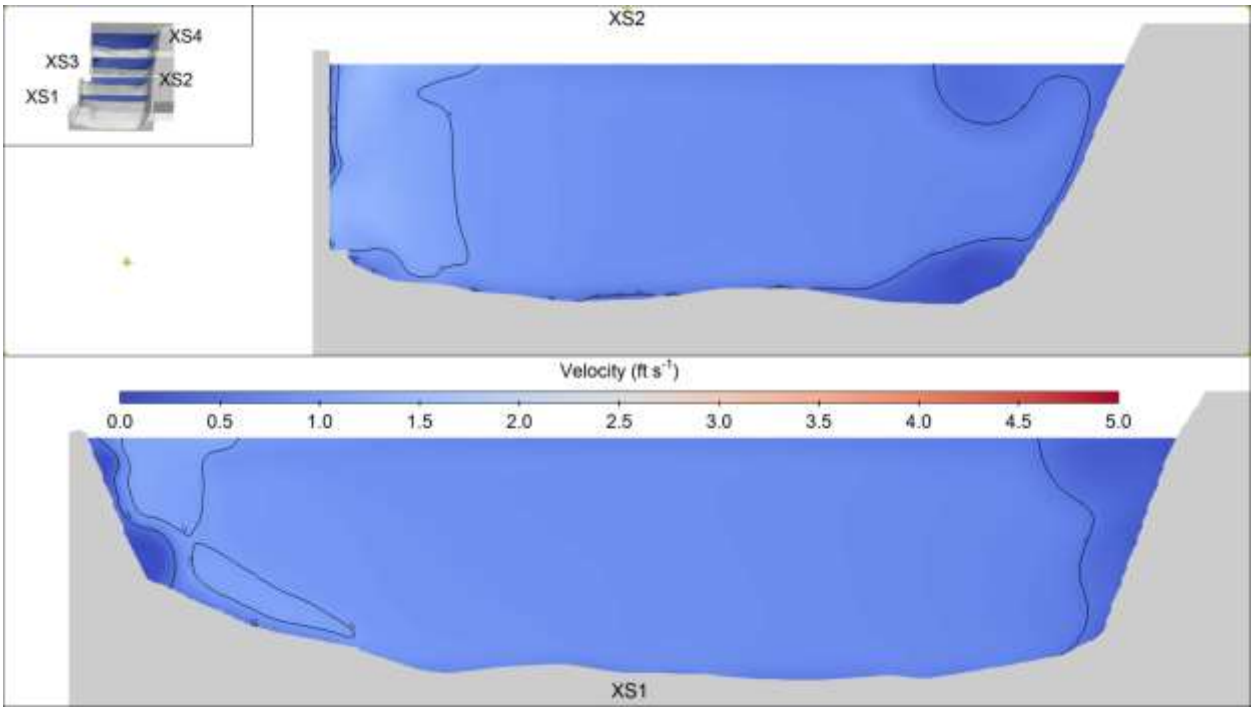

Figure 4-46: Velocity Contours on Cross-Sections for Case 3

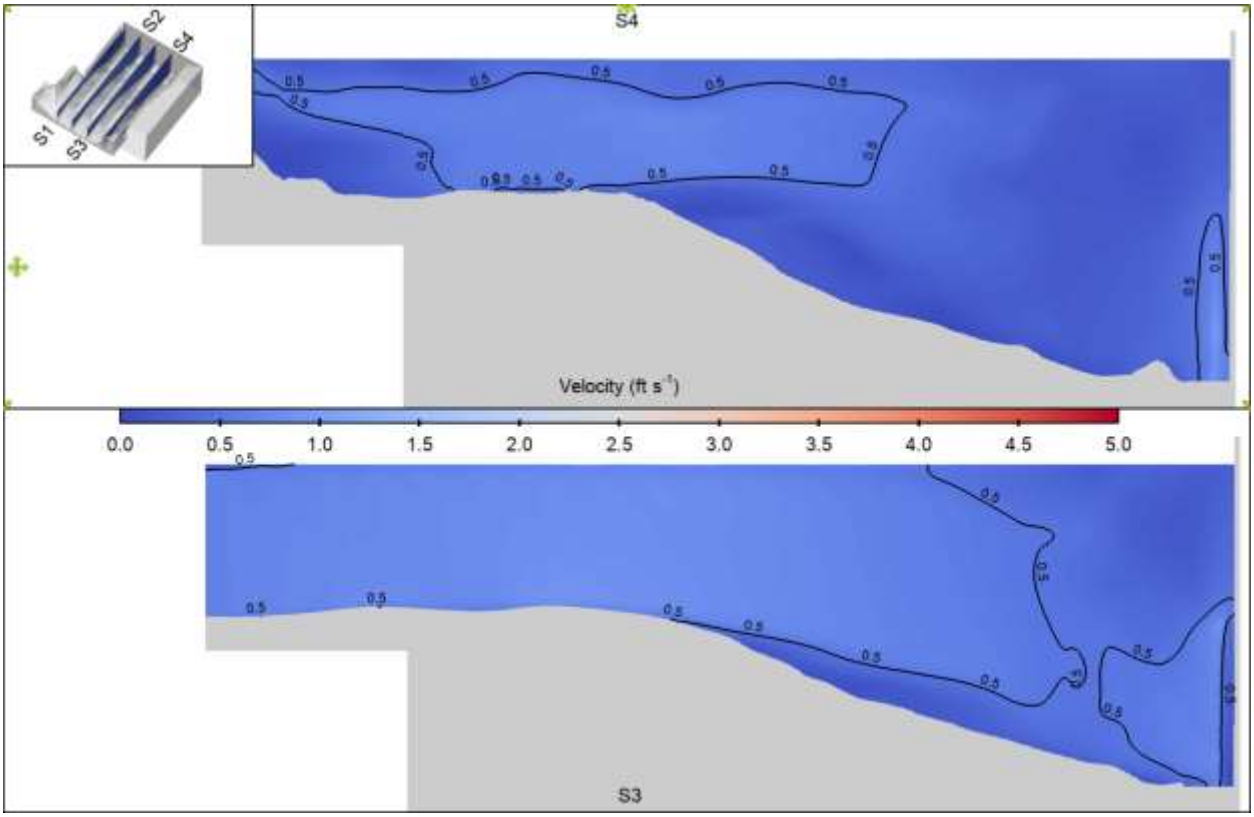

Figure 4-49: Velocity Contours on Sections for Case 3

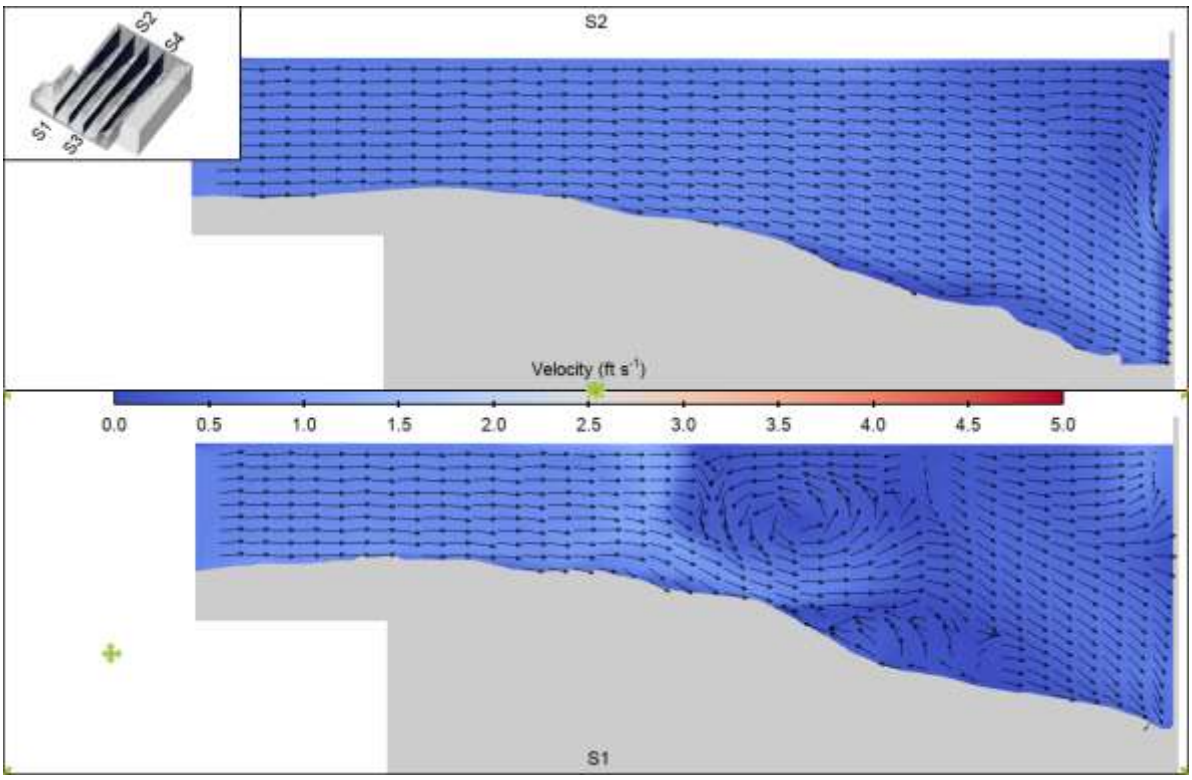

Figure 4-50: Velocity Vectors on Sections for Case 3

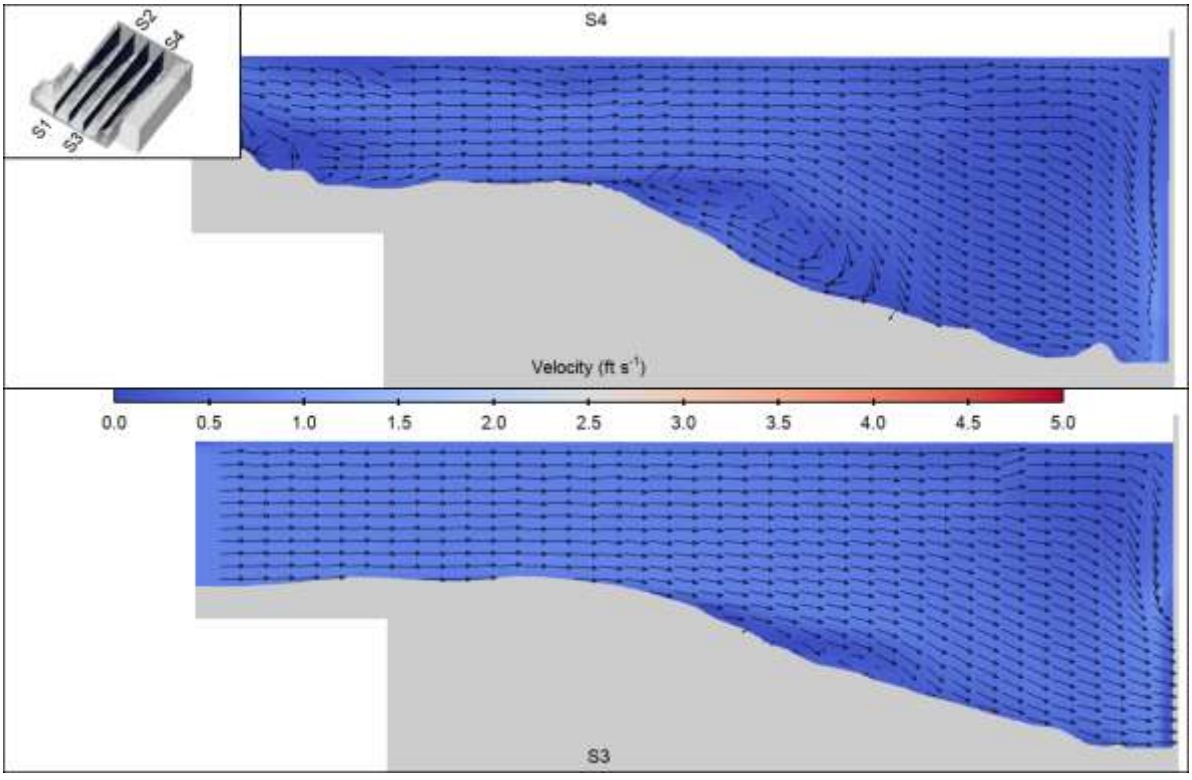

Figure 4-51: Velocity Vectors on Sections for Case 3

The velocity patterns show a recirculation area along the fish elevator structure. Flow approaches the fishway entrance parallel to the powerhouse structure. The streamlines indicate flow entering the fishway originates from the left bank (viewing downstream) of the powerhouse channel.

4.3 E.L. Field Powerhouse Tailrace Model

Two simulations for the tailrace model were analyzed and plots showing velocity contour and vectors at multiple depths were exported. The figures depicting streamlines are colored by velocity and model inlet. The red colored streamlines enter the model domain through the AWS and the cyan lines would discharge through the powerhouse.

4.3.1 Case 1 – 5% Exceedance Tailwater Level

The 5 percent exceedance model assigns 3,300 cfs through each unit for a total powerhouse flow of 6,600 cfs. The AWS is operating at 100 cfs under this scenario. The downstream tailwater condition was determined from the 1983 Tailwater Curve provided to HDR via Email on 2/12/2021. The river flow for the 5% exceedance is approximately 26,000 cfs. At this flow, the tailwater at the downstream end of the tailrace is approximately 58.36 ft. Figure 4-52 shows the velocity contours and vectors at the water surface and depths of 2 ft, 5 ft, and 10 ft. Multiple profiles showing velocity contours and vectors are shown on Figure 4-53. The streamlines colored by velocity are shown on Figure 4-54. Figure 4-55 shows streamlines colored by model outlet. The blue colored streamlines enter the model domain through the AWS and the red lines would discharge through the powerhouse.

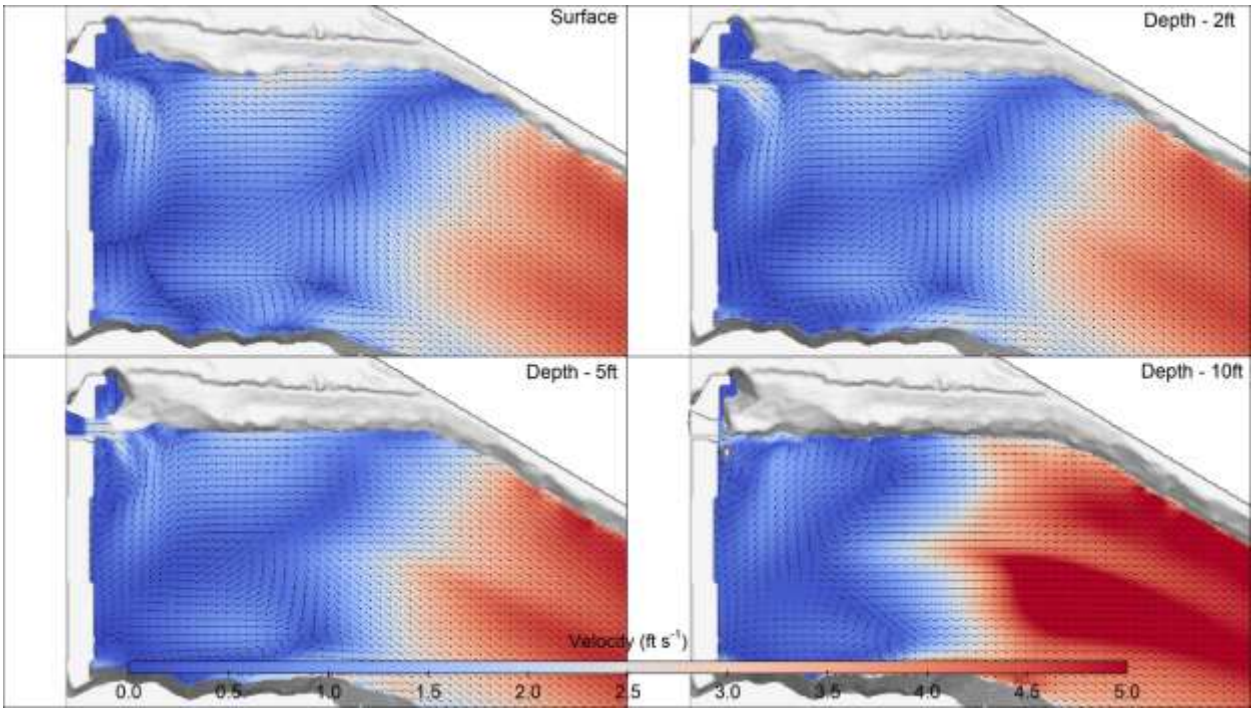

Figure 4-52: Velocity Contours and Vectors at Depth for Case 1

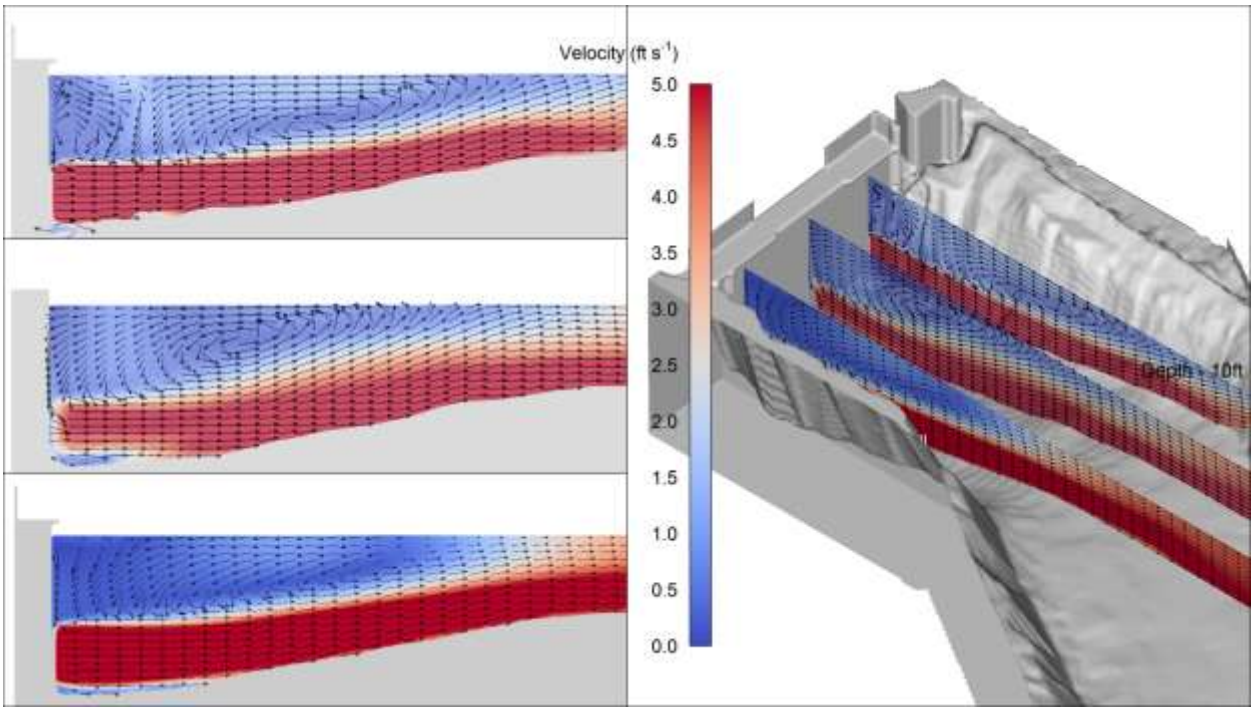

Figure 4-53: Velocity contours and Vector Profiles for Case 1

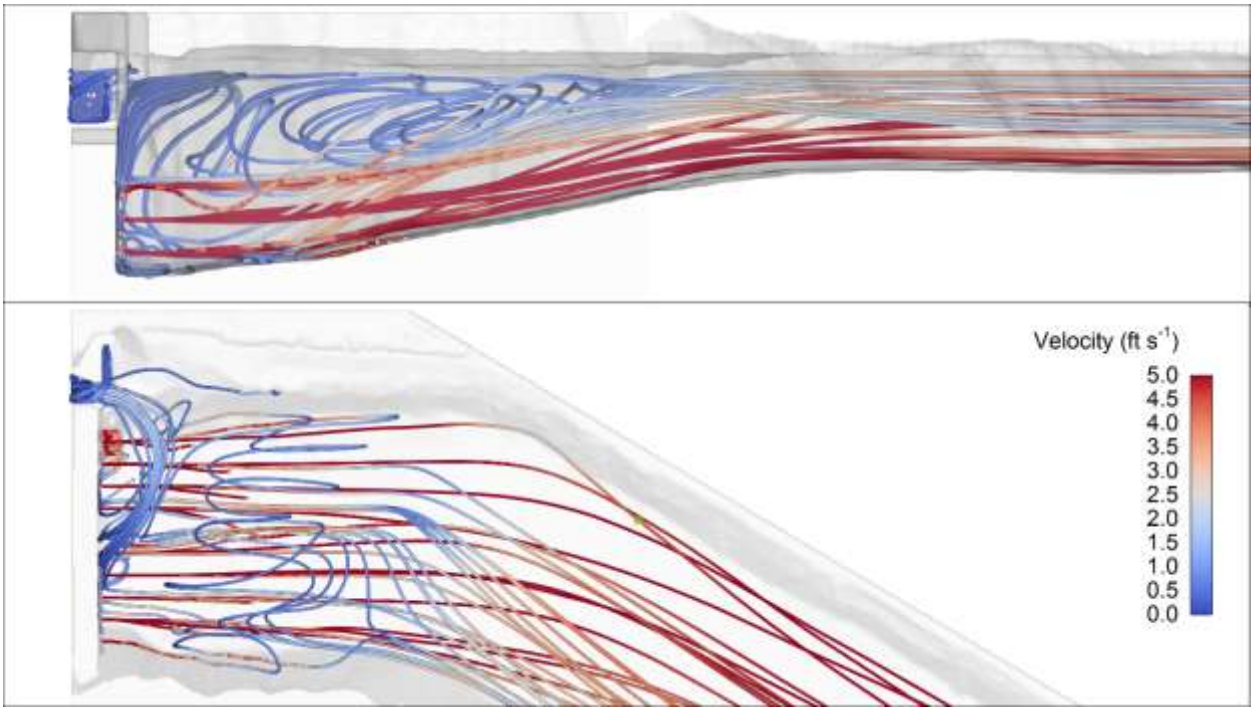

Figure 4-54: Streamlines Colored by Velocity Showing Flow Patterns for Case 1

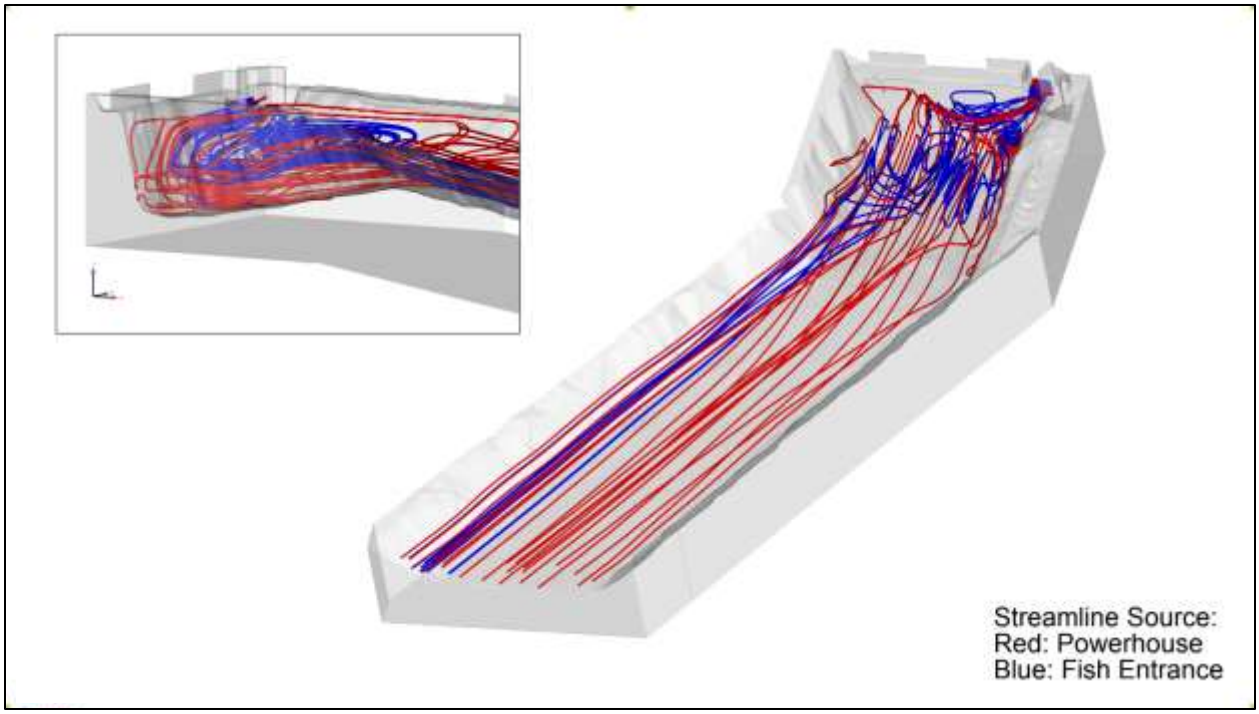

Figure 4-55: Streamlines Colored by Model Outlet Showing Flow Patterns for Case 1

The velocity patterns show a recirculation area above the powerhouse discharges. The recirculation creates two areas where flow is separated near the powerhouse discharge. The flow from the AWS mixes with the powerhouse discharge. The entrance to the AWS shows velocities below 4.0 ft per second. The rock outcrop downstream of the outlet directs flow to the center of the tailrace allowing the flow to mix with the powerhouse discharge.

4.3.2 Case 2 – 50% Exceedance Tailwater Level

The 50 percent exceedance model assigns 3,300 cfs through each unit for a total powerhouse flow of 6,600 cfs. The downstream tailwater condition was determined from the 1983 Tailwater Curve provided to HDR via Email on 2/12/2021. The river flow for the 50% exceedance is approximately 6,755 cfs. At this flow, the tailwater at the downstream end of the tailrace is approximately 53.2 ft. The AWS is operating at 100 cfs under this scenario. Figure 4-56 shows the velocity contours and vectors at the water surface and depths of 2 ft, 5 ft, and 10 ft. Multiple profiles showing velocity contours and vectors are shown in Figure 4-57. The streamlines colored by velocity are shown in Figure 4-58. Figure 4-59 shows streamlines colored by model outlet. The blue colored streamlines enter the model domain through the AWS and the red lines would discharge through the powerhouse.

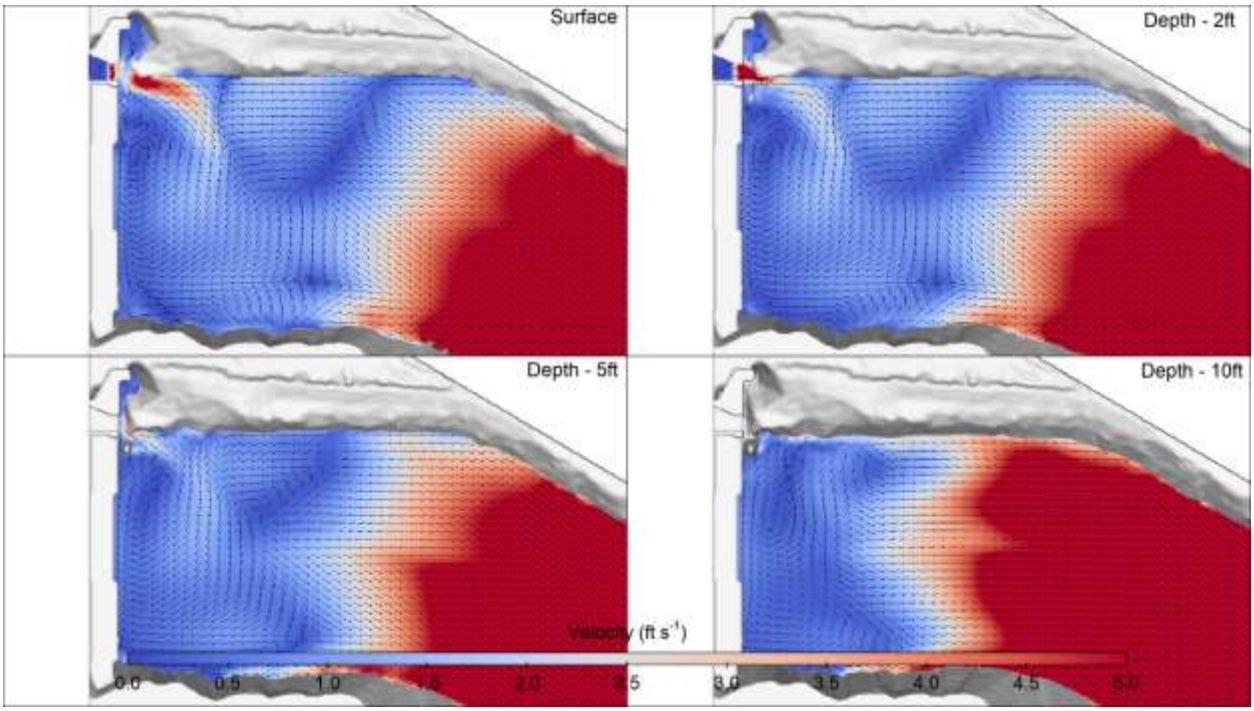

Figure 4-56: Velocity Contours and Vectors at Depth for Case 2

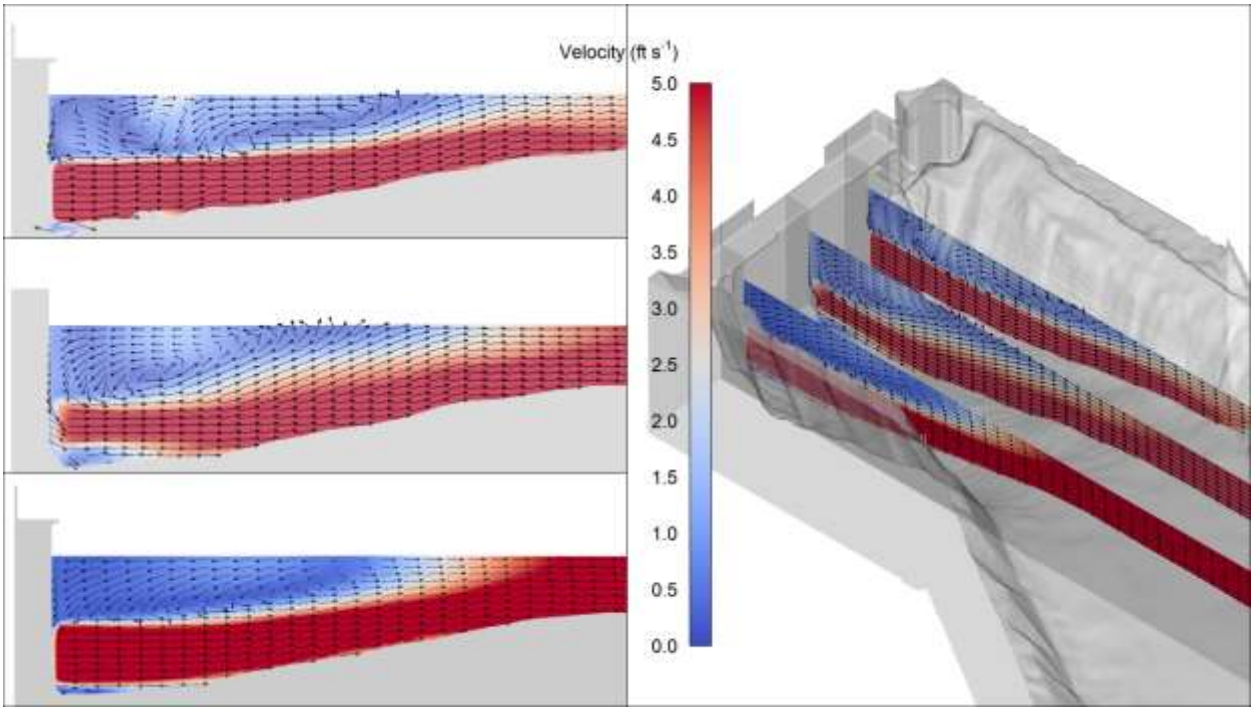

Figure 4-57: Velocity Contours and Vector Profiles for Case 2

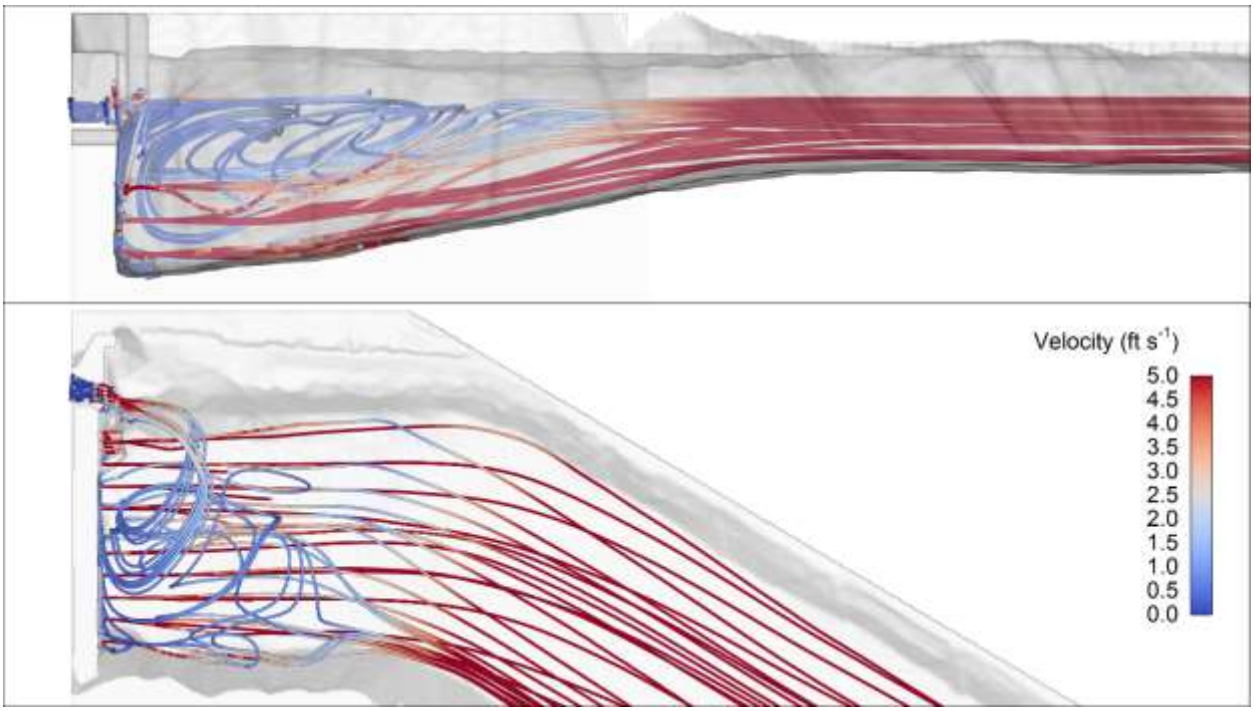

Figure 4-58: Streamlines Colored by Velocity Showing Flow Patterns for Case 2

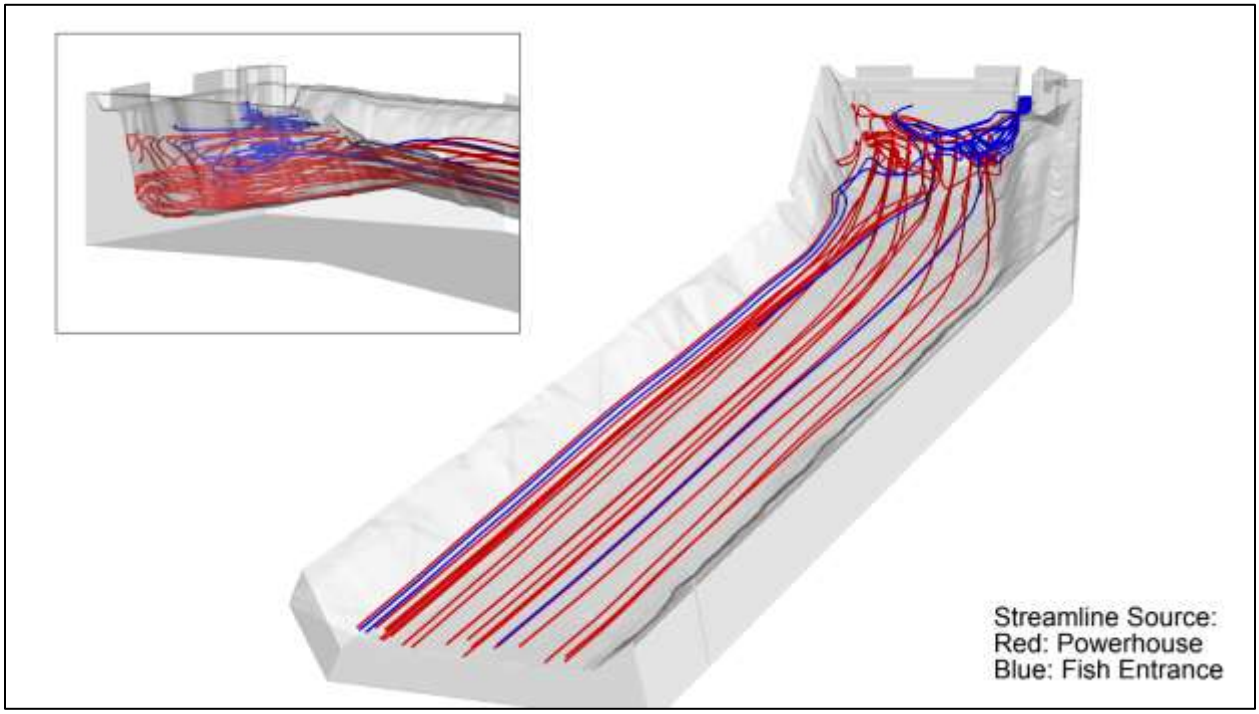

Figure 4-59: Streamlines Colored by Model Outlet Showing Flow Patterns for Case 2

The velocity patterns show a recirculation area above the powerhouse discharges. The recirculation creates two areas of flow separation near the powerhouse discharge. The flow from the AWS mixes with the powerhouse discharge. The velocity near the AWS

outlet is above 5.0 ft per second and the flow path was limited to the top 5 ft of the water column during modeling.

5 Conclusions

Three CFD models were developed to help assess the hydraulic conditions near the Pawtucket Dam fish ladder and the E.L. Field Powerhouse forebay and tailrace. Multiple simulations were run for each model and the results were graphically presented.

The Pawtucket Fish Ladder simulations showed increased velocities over the baffles placed in the fish ladder slots and a recirculation area was present in the 180° near the inside wall. The fish ladder entrance showed an area of flow recirculation or cross flow for the modeled events. The bypass weirs showed increased velocities at the gaps.

The E.L. Field Powerhouse forebay CFD model showed a large recirculation area upstream of the AWS. Flow entering the AWS was limited to the upper portion of the water column and originated along the left bank (viewing downstream) of the channel. The AWS flow would travel from the left bank to the upstream powerhouse face before turning parallel to the powerhouse face and entering the AWS.

The E.L. Field Powerhouse tailrace CFD model showed a mixed flow at the downstream boundary. Flow exiting the river side AWS was immediately mixed with the powerhouse discharge. Flow from the powerhouse would change direction and flow toward the powerhouse, mixing the AWS flow into the water column. The low tailrace elevation shows a limited flow path and velocities exceeding 5.0 ft per second at the AWS outlet.

SUBJECT: Response to June 23, 2021 FERC Staff Recommendations on Requested Modifications to Approved Studies – Fish Passage Survival

---

Background

Boott Hydropower, LLC (Boott), a subsidiary of Central Rivers Power US, LLC, is the Licensee, owner, and operator of the 20-megawatt Lowell Hydroelectric Project (Project) (FERC No. 2790). Boott operates and maintains the Project under license from the Federal Energy Regulatory Commission (FERC or Commission). The Project's existing license expires on April 30, 2023. Boott is pursuing a new license for the Project using the Commission's Integrated Licensing Process (ILP). Pursuant to the ILP process, Boott submitted a Revised Initial Study Report (ISR) to FERC on February 25, 2021. Comments on the February 25, 2021 Revised ISR, including requests for study modifications, were filed by the Massachusetts Division of Fisheries and Wildlife (MDFW), the National Marine Fisheries Service (NMFS), and the U.S. Fish and Wildlife Service (FWS). Boott filed responses to resource agency comments on May 28, 2021.

On June 23, 2021, the Commission issued a Determination on Requests for Study Modifications for the Lowell Hydroelectric Project. The letter contained the determination on requests for modifications to the approved study plan for the ongoing relicensing of the Lowell Project. Among the resource studies identified in the June 23 FERC determination letter was the Fish Passage Survival Study. Specific to the Fish Passage Survival Study, FERC indicated Boott should "*rerun the model for adult eels, adult alosines, and juvenile alosines for low, medium, and high flow conditions (i.e., 75, 50, and 25 percent exceedance flows), using the calibrated lambda values discussed above, with the assumption that fish routing will occur in proportion to flows*".

This technical memo provides a summary of the methodology and findings related to the FERC request for additional analysis for the Fish Passage Survival Study.

Methodology

To address the FERC request above, the following information was required:

DRAFT

- Mean body length and associated standard deviation for anticipated outmigrating populations of adult river herring, adult American shad, juvenile alosines, and adult American eels;
- Lowell inflow for the downstream passage season for spring (i.e., May to June) and fall (i.e., October to November) migrants for the 75%, 50%, and 25% exceedance conditions;
- Set of physical parameter values and estimates for characterizing the two Kaplan turbine units housed in the E.L. Field powerhouse;
- Calibrated values of lambda for use in the new downstream passage models for adult alosines and adult eels (calibration to be informed using estimated turbine survival rates obtained during 2019-2020 field studies for adult eels and alosines);
- Proportional distribution among available downstream passage routes; and
- Non-turbine route-specific survival estimates.

All estimates of fish passage survival were calculated using the USFWS Turbine Blade Strike Analysis (TBSA) Tool. The TBSA estimates the fraction of a population of fish that are lost during downstream passage at a hydroelectric project. TBSA simulates passage of a normally distributed population of fish described by a user-defined mean length and associated standard deviation of length. The TBSA then routes the theoretical population through potential downstream passage routes at the project (e.g., turbine unit, downstream bypass or spill) using a user-defined set of proportions. The TBSA Tool provides an estimate of total passage survival for the subset of fish determined to pass the project via each user-input route. The TBSA uses turbine specific parameters to estimate blade strike for fish passing through the powerhouse units and incorporates user-defined survival rates for non-turbine routes.

Fish Size Information:
Body size information for the four target fish species used in this analysis is presented in Table 1. Species-specific length ranges are those originally presented in the Fish Passage Survival Study. For modeling purposes a normal distribution was assumed and the mid-point of the species-specific range was adopted as the mean value. An associated standard deviation was calculated as 1/3 the value between the mean and upper or lower bound of the range. This ensured that approximately 99% of the overall expected size range for each species would be considered.

Table 1. Size range (i.e., minimum – maximum), average, and associated standard deviation for target diadromous fish species.

Species	Minimum (inches)	Maximum (inches)	Average (inches)	Std. Dev.
River herring (Adult)	9	13	11	0. 7
American shad (Adult)	15	23	19	1.3
Juvenile Alosine	2	6	4	0.7
American Eel	25	41	33	2. 7

DRAFT

Lowell Inflow Conditions:

FERC requested modeled passage survival under low, medium and high flow conditions. Flow duration curves for the spring (i.e., May-June) and fall (i.e., October-November) were reviewed (Figure 1). Values for the 25%, 50%, and 75% exceedance conditions were considered as part of this analysis and are presented in Table 2.

Table 2. Merrimack River inflow at Lowell for the 25%, 50%, and 75% exceedance condition during the spring (May-June) and fall (September-October) seasons.

Percent Exceedance	Spring (cfs)	Fall (cfs)
25	11,239	8,835
50	6,755	4,989
75	4,129	3,038

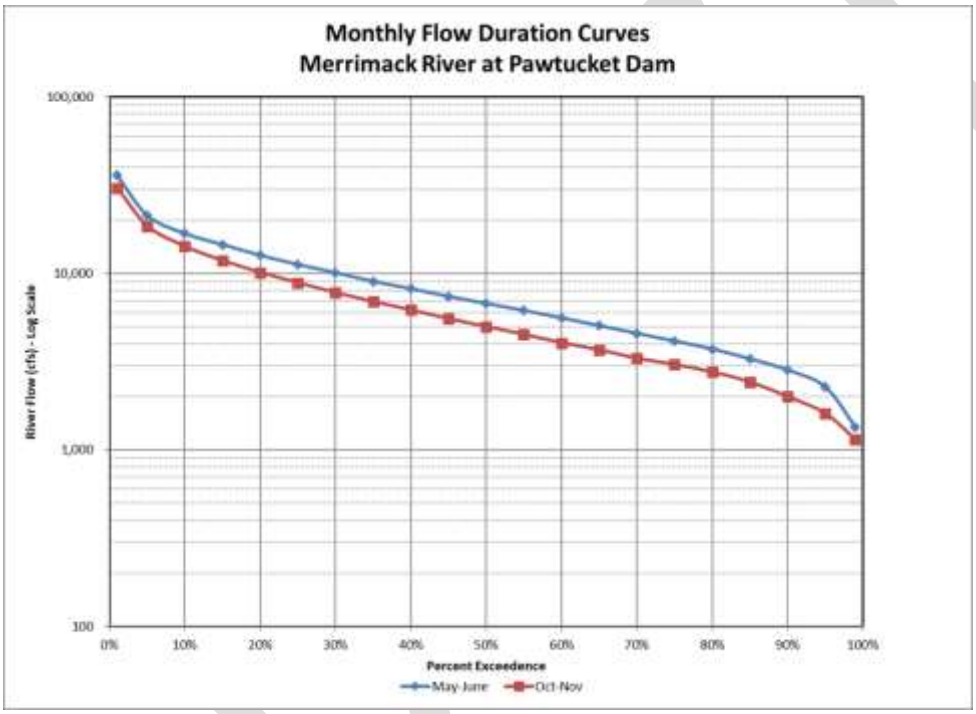

Figure 1. Flow duration curves for the two month periods of May-June and October-November at Lowell.

Lowell Turbine Parameters:

Table 3 provides a summary of the descriptive parameters for the two Kaplan turbines in operation at the E.L. Field powerhouse. These values were previously used during analyses presented in the Revised ISR.

Table 3. Characteristics of Kaplan turbines in operation at the Lowell Project E.L. Field Powerhouse.

Turbine Type	Kaplan
Runner Diameter (ft)	12.7
Number of Blades	5
Turbine Discharge (cfs)	3,300
Discharge at Optimum Efficiency (%)	81.3%
Net Head (ft)	39
Speed (rpm)	120
Turbine Efficiency (%)	92.8

Calibration of Lambda:

In addition to the turbine parameters described above, the strike mortality correlation factor, lambda (λ) is also required to run simulations of downstream fish passage survival using the USFWS TBSA Tool. The Fish Passage Survival Study provided by Boott as part of the Revised ISR, utilized recommended starting values of 0.2 for alosines and 0.4 for adult eels. As part of comments on the Revised ISR, the resource agencies requested the use of calibrated TBSA models to estimate total project survival. To accomplish this, multiple simulations were run which held the project-specific turbine parameters and fish population characteristics constant while allowing the correlation factor to vary. These simulations were run until a value of lambda was identified which produced a TBSA estimate of turbine passage survival equivalent to that observed during field studies conducted during 2019 and 2020. The resulting values for lambda used as part of this analysis are presented in Table 4.

Table 4. Correlation factor values (λ) used to calibrate turbine passage component of TBSA models to approximate field-derived turbine survival rates.

Fish Species (life stage)	Field-derived Turbine Survival Rate	Correlation Factor (λ)	Resulting TBSA Turbine Survival Rate
River herring (Adult)	73.9% (75% CI = 68.8%-79.1%)	0.7	73.9%
American shad (Adult)	35.5% (75% CI = 25.8%-45.2%)	1	34.6%
Juvenile Alosine	-	0.2*	-
American Eel	75.0% (75% CI = 70.6%-79.4%)	0.2	75.0%

*As no field-derived estimate of juvenile alosine survival was available, the standard USFWS value of λ =0.2 was used

Passage Route Distribution:

In their June 23, 2021 Determination on Requests for Study Modifications, FERC requested that additional downstream passage survival analyses assume that fish routing among available passage routes occur proportional to flow. Table 5 summarize the distribution of water at the Lowell Project under each of the seasonal inflow conditions presented in Table 2. In all cases it was assumed that the downstream bypass was in operation and passing 2% of station capacity. Inflow of up to 6,600 cfs was assumed to pass via the two turbine units. Any inflow in excess of

DRAFT

the downstream bypass and powerhouse was assumed to pass downstream via spill into the bypassed reach.

Table 5. Distribution of inflow at the Lowell Project under the 25%, 50%, and 75% exceedance conditions during the spring and fall fish migration periods.

Condition	Inflow (cfs)	Discharge (cfs)			Distribution (%)		
		Turbine	Bypass	Spill	Turbine	Bypass	Spill
Spring - 25% Exceedance	11,239	6,600	132	4,507	59%	1%	40%
Spring - 50% Exceedance	6,755	6,600	132	23	98%	2%	0%
Spring - 75% Exceedance	4,129	4,046	83	0	98%	2%	0%
Fall - 25% Exceedance	8,835	6,600	132	2,103	75%	1%	24%
Fall - 50% Exceedance	4,989	4,889	100	0	98%	2%	0%
Fall - 75% Exceedance	3,038	2,977	61	0	98%	2%	0%

Non-Turbine Mortality Rates:
Determination of whole-station survival for a theoretical fish population using the TBSA requires user-defined input to characterize survival of individuals passing downstream via any non-turbine passage routes. In this case the field-derived passage rates for alosines and eels observed during the 2019 and 2020 studies were utilized. These values are summarized in Table 6.

Table 6. Field-derived or assumed non-turbine route mortality rates for species/life stages at Lowell.

Fish Species (life stage)	Bypass	Spill	Notes
River herring (Adult)	12.2%	10.8%	Spill was limited to 1 individual; used rate for adult shad as a surrogate
American shad (Adult)	17.4%	10.8%	
Juvenile Alosine	12.0%	11.0%	Used adult alosine rates as a surrogate
American Eel	0.0%	0.0%	Spill based on 4 individuals; bypass assumed to be equivalent

Results

Species-specific body size information, turbine parameters, assumed passage route distribution information, and available non-turbine survival rates were combined using the TBSA Tool to generate estimates of passage survival for adult river herring, adult American shad, juvenile alosines and adult American eels. Estimates were generated for a high flow condition (i.e., 25% exceedance condition), mid flow condition (i.e., 50% exceedance condition) and a low flow condition (i.e., 75% exceedance condition). Results are presented in Tables 7 (adult river herring, 8 (adult American shad), 9 (juvenile alosines), and 10 (adult American eels). In general, whole station survival was greatest under the high flow condition. The high flow condition resulted in 40% (spring) and 24% (fall), respectively, of flow (and fish) passing via spill into the downstream bypass. Downstream passage during the mid and low flow condition was limited

DRAFT

to use of the downstream bypass or via the turbine units. As evidenced in Tables 7-9, blade strike at the turbine units was the primary cause of mortality under most species-inflow condition combinations.

Table 7. TBSA estimated rates for turbine strike, bypass failure, and passage survival for adult river herring under a high, mid, and low flow condition at Lowell.

Condition	Turbine Strikes	Bypass Failures	Survival
Spring - 25% Exceedance	14.7%	6.5%	78.8%
Spring - 50% Exceedance	24.2%	0.0%	75.8%
Spring - 75% Exceedance	35.8%	0.0%	64.2%

Table 8. Estimates of rates for turbine strike, bypass failure, and passage success for adult American shad under a high, mid, and low flow condition at Lowell.

Condition	Turbine Strikes	Bypass Failures	Survival
Spring - 25% Exceedance	42.2%	2.7%	55.1%
Spring - 50% Exceedance	64.5%	0.6%	34.9%
Spring - 75% Exceedance	79.4%	0.3%	20.3%

Table 9. Estimates of rates for turbine strike, bypass failure, and passage success for juvenile alosines under a high, mid, and low flow condition at Lowell.

Condition	Turbine Strikes	Bypass Failures	Survival
Fall - 25% Exceedance	1.1%	2.8%	96.1%
Fall - 50% Exceedance	3.2%	0.7%	96.1%
Fall - 75% Exceedance	3.9%	0.2%	95.9%

Table 10. Estimates of rates for turbine strike, bypass failure, and passage success for adult American eel under a high, mid, and low flow condition at Lowell.

Condition	Turbine Strikes	Bypass Failures	Survival
Fall - 25% Exceedance	16.7%	0.0%	83.3%
Fall - 50% Exceedance	27.2%	0.0%	72.8%
Fall - 75% Exceedance	33.9%	0.0%	66.1%

1 Introduction and Background

Boott Hydropower, LLC (Boott or Licensee) is the Licensee, owner, and operator of the 20.2-megawatt Lowell Hydroelectric Project (Project or Lowell Project) (FERC No. 2790). Boott operates and maintains the Project under a license from the Federal Energy Regulatory Commission (FERC or Commission). The Project's existing license expires on April 30, 2023. Boott is pursuing a new license for the Project using the Commission's Integrated Licensing Process (ILP) as defined in 18 Code of Federal Regulations (C.F.R.) Part 5.

In accordance with 18 C.F.R. § 5.15, Boott has conducted studies as provided in the study plan and schedule approved in the Commission's March 13, 2019 Study Plan Determination (SPD) for the Project.[1] This report describes the methods and results of the approved Resources, Ownership, Boundaries, and Land Rights Study conducted in support of a new license for the Project.

1.1 Project Description and Background

The Lowell Project is located at river mile (RM) 41 on the Merrimack River in the City of Lowell in Middlesex County, Massachusetts, with an impoundment extending approximately 23 miles upstream into Hillsborough County, New Hampshire. The existing Lowell Project consists of:

1) A 1,093-foot-long, 15-foot-high masonry gravity dam (Pawtucket Dam) that includes a 982.5-foot-long spillway with a crest elevation of 87.2 feet National Geodetic Vertical Datum 1929 (NGVD 29) topped by 5-foot-high pneumatically-operated crest gates deployed in five independently-operable zones;
2) A 720-acre impoundment with a normal maximum water surface elevation of 92.2 feet NGVD 29;
3) A 5.5-mile-long canal system which includes several small dams and gatehouses;
4) A powerhouse (E.L. Field) which uses water from the Northern Canal and contains two turbine-generator units with a total installed capacity of 15.0 megawatts (MW);
5) A 440-foot-long tailrace channel;
6) Four powerhouses (Assets, Bridge Street, Hamilton, and John Street) housed in nineteenth century mill buildings along the Northern and Pawtucket Canal systems containing 15 turbine-generator units with a total installed capacity of approximately 5.1 MW;

[1] The Commission issued a Revised Process Plan and Schedule on June 12, 2020.

7) A 4.5-mile-long, 13.8-kilovolt transmission line connecting the powerhouses to the regional distribution grid;

8) Upstream and downstream fish passage facilities including a fish elevator and downstream fish bypass at the E.L. Field Powerhouse, and a vertical-slot fish ladder at the Pawtucket Dam; and

9) Appurtenant facilities.

At the normal pond elevation of 92.2 feet NGVD 29 (crest of the pneumatic flashboards), the surface area of the impoundment encompasses an area of approximately 720 acres. The gross storage capacity between the normal surface elevation of 92.2 feet and the minimum pond level of 87.2 feet is approximately 3,600 acre-feet. The Project operates essentially in a run-of-river (ROR) mode using automatic pond level control and has no usable storage capacity.

The Project's primary features are located along the Merrimack River in the City of Lowell, Massachusetts. The City of Lowell was founded in the early 1820s by Boston merchant capitalists and became one of the most significant planned industrial cities in America. Lowell's factory system, which used the waterpower of the Merrimack River, incorporated new technologies to provide for the mass production of cotton cloth in mills throughout the city (National Park Service [NPS] 1981). Lowell established the pattern for large-scale waterpower development for the next 50 years.

Several Project facilities are located within overlapping locally, state, and nationally designated parks and historic properties/preservation districts. The Project's Pawtucket Dam and E.L. Field Powerhouse are located along the mainstem of the Merrimack River. The existing Project's two-tiered network of man-made canals extends throughout downtown Lowell. In addition to the Pawtucket Dam and hydroelectric developments, the existing Project also includes miscellaneous civil works in the City of Lowell, including the Guard Lock and Gates, Moody Street Feeder Gatehouse, Lawrence Dam, Hall Street Dam, Tremont Wasteway, Lower Locks and Dam, Swamp Locks and Dam, Merrimack Dam, Rolling Dam, and Boott Dam. As discussed in Boott's December 2, 2020 DLA for the Project, operation of the canal units is no longer economically feasible, and Boott has proposed to remove the downtown developments (Assets, Bridge Street, Hamilton, and John Street) and associated canal infrastructure from the Project's FERC license. Boott is not proposing to restart or continue generation at these four developments.

The canal system, the downtown mill sites, and many of the Project's civil works, are contributing resources to Lowell Locks and Canals National Historic Landmark (NHL) District. The canal system and many Project facilities are also located within the Lowell National Historical Park (LNHP) managed by the NPS and the larger Lowell Historic Preservation District. The LNHP was established by Congress in 1978 to "preserve and interpret the nationally significant historical and cultural sites, structures, and districts in Lowell, Massachusetts, for the benefit and inspiration of present and future generations." The park is by design a partnership park in which federal, state, and local governments as well as the private sector and local community carry out the legislative intent of the

park unit. The LNHP is also listed on the National Register of Historic Places (NRHP), and certain properties within the park overlap with properties in the NHL District.

The Lowell Heritage State Park, established in 1974 as a precursor to the LNHP, is also located within the City of Lowell and is comprised of linear greenways along the Merrimack River and canal system and a collection of historic buildings and structures related to the industrial development of the city. These buildings and structures include Project features and properties located within the NHL District. The Lowell Heritage State Park is operated by the Massachusetts Department of Conservation and Recreation (MADCR) and features exhibits created in partnership with the NPS (MADCR 2018). With the exception of the Rynne Bathhouse, all of the built resources within the Lowell Heritage State Park fall within the Lowell Historic District, designated by the City of Lowell to "…ensure that development activities within the district are consistent with the preservation of its 19th century setting" (MADCR 2014). Portions of the Lowell Heritage State Park also overlap with the Lowell Locks and Canals NHL District and the LNHP.

Ownership, boundaries, and land/access rights of the downtown canal system in Lowell are complex. The existing Project is situated within several different and overlapping parks, and preservation/conservation districts. The park is by design a partnership park in which federal, state, and local governments as well as the private sector and local community carry out the legislative intent of the park unit.

On April 30, 2018, Boott initiated the ILP by filing a Pre-Application Document (PAD) and Notice of Intent (NOI) with the Commission. Major ILP milestones to-date are presented below in Table 1-1.

Table 1-1. Major ILP Milestones Completed

Date	Milestone
April 30, 2018	PAD and NOI Filed
June 15, 2018	Scoping Document 1 (SD1) Issued by FERC
July 17, 2018	FERC Agency and Public Scoping Meetings Conducted
July 18, 2018	Project Site Visit Held
September 27, 2018	Scoping Document 2 (SD2) Issued by FERC
September 28, 2018	Proposed Study Plan (PSP) Filed
October 18 & 19, 2018	PSP Meeting Conducted
January 28, 2019	Revised Study Plan (RSP) Filed
March 13, 2019	FERC Issued SPD
February 25, 2020	Initial Study Report (ISR) Filed
March 11, 2020	ISR Meeting
June 12, 2020	FERC Issued Revised Process Plan and Schedule

September 30, 2020	Revised ISR Filed
December 2, 2020	Draft License Application (DLA) Filed
February 25, 2021	Revised ISR Filed
April 30, 2021	Final License Application (FLA) Filed

Boott has continued consultation with stakeholders regarding the approved studies as required by the Commission's SPD. In accordance with the approved study plan, Boott has also provided stakeholders with Quarterly ILP Study Progress Reports that include a description of study activities conducted during the previous quarter, activities expected to occur in the next quarter, and identified variances from the approved study plan.

2 Study Goals and Objectives

The goal of this study is to determine current ownership of resources within the canal system and existing Project Boundary, and document maintenance responsibilities, access rights, and FERC jurisdiction. The specific objectives of this study are as follows:

- Determine the current ownership of resources within the canal system in a comprehensive manner;
- Record maintenance responsibilities and obligations to resources within the canal system;
- Clarify FERC jurisdiction;
- Document recreational, educational, or other land access rights to resources within the canal system; and
  Work with the MADCR, NPS, City of Lowell, and other parties to develop a Geographic Information System (GIS) database of resources, ownership, boundaries, and land rights.

3 Study Area

In accordance with the Commission's SPD, the study area for the Resources, Ownership, Boundaries, and Land Rights Study includes the existing FERC Project Boundary and associated structures in the downtown area (Appendix A).

4 Methodology

4.1 Literature Review and Analysis

Boott conducted desktop research and a literature review to compile and review available ownership and rights documentation to obtain a better understanding of the rights and responsibilities related to resources within the Project Boundary. As appropriate and relevant, public guidance and conceptual planning and/or management documentation was reviewed by Boott including the following:

- The 1980 *Details of the Preservation Plan*[2] prepared by the Lowell Historic Preservation Commission (LHPC), containing technical materials including a description of agreed-upon agency roles at the City, State, and Federal level.
- The 1981 *Final General Management Plan* (FGMP)[2] developed by NPS to provide a basis for visitor use, resource management, and general development within the LNHP.
- The 1990 *Preservation Plan Amendment*[2] developed by the LHPC summarizes accomplishments of the LNHP and outlines its proposed activities.
- The 1991 *Memorandum of Understanding* (MOU) executed by MADCR, NPS, and Boott for the purpose of maintaining, managing, and operating the Lowell canal system (MOU 1991).

On December 18, 2019, Boott held a Lowell Hydroelectric Project Study Workshop (Study Workshop)[3] with stakeholders. During the Study Workshop it was suggested that three legal documents establish most of the ownership, responsibilities, and land rights to the Lowell canal system. The 1984 *Deed, Bill of Sale and Grant of Easements*, also known as the *"Great Deed"* (Appendix B) details the sale of portions of the Project from the Proprietors of the Locks and Canals on the Merrimack River (Proprietors)[4] to Boott, as well as associated access and repair easements. The 1986 *Order of Taking* (Appendix C) details the take of properties, rights, and responsibilities from Boott and Proprietors to the Commonwealth, operating through MADCR. The 1995 *Grant of Easement* (Appendix D) describes the easement rights provided to the NPS from MADCR for specific properties and parcels around the canal system.

[2] This plan was approved by FERC on March 20, 2019 as a Comprehensive Plan under section 10(a)(2)(A) of the Federal Power Act.

[3] The meeting minutes of the December 18, 2019 Study Workshop were appended to the ISR filed with FERC on February 25, 2020.

[4] Proprietors is an existing limited liability corporation founded on June 27, 1792 to construct the Pawtucket Canal. In the early 1960s, the company was acquired by a group of Lowell investors who restructured its assets. Boott acquired much of the Lowell Project, including the Pawtucket Dam, from the Proprietors in December 1984.

4.2 Geographic Information System Database

The GIS Database was developed using ESRI's ArcMap, ArcCatalog and ArcGIS Online. The GIS database has been published to create an existing service feature in ArcGIS Online. Incorporated into the GIS database is a point feature class with surveyed plans, .tiff and .jpg images. The Facility Location point feature class was created by spatially locating each parcel centroid listed on the existing exhibit maps relevant to any know easement or right of way along the power canals in Lowell, MA. The point features known as "Facility Location" were spatially located from several sources including existing exhibit maps, Google Earth and the LNHP website. Real Property GIS files were obtained from the City of Lowell Assessors office in January 2021 and are used to display background data as well as locating parcel ID and owner. Additionally, to enhance the user experience, each exhibit map was georeferenced to the parcel centroid in an effort to display the correct location within the canal system. Exhibit map images in the geodatabase appear as a pop-up in the known location.

This features in ArcGIS were converted into a publicly-accessible GIS database using ArcGIS Experience Builder and can be viewed here:
https://experience.arcgis.com/experience/f9e9b945e80c49daa767f50e218e0181/

5 Study Results

Pursuant to the approved study plan, Boott reviewed several sources to understand the ownership, rights, and responsibilities related to resources within the Project Boundary. The results of this analysis are divided into the following sections:

- **Section 5.1 Conceptual Planning of the Lowell Canal System:** identifies responsibilities and rights as presented in comprehensive plans and public planning documents issued for development and management of the Lowell canal system.
- **Section 5.2 Ownership of the Lowell Canal System:** presents the complex legal ownership of structures of the Lowell canal system based on a review of the 1984 *Great Deed* and 1986 *Order of Taking*.
- **Section 5.3 Easement Rights to the Lowell Canal System:** presents the legal easement rights to structures of the Lowell canal system based on a review of the 1984 *Great Deed*, the 1986 *Order of Taking*, and the 1995 *Grant of Easement*.
- **Section 5.4 Resource Rights in the Lowell Canal System:** identifies specific resources and their ownership and/or easement rights based on a review of public planning documents and the 1984 *Great Deed*, the 1986 *Order of Taking*, and the 1995 *Grant of Easement*.
- **Section 5.5 Historical Management Agreements:** discusses the two known historical management agreements which reflect the parties understanding of legal ownership, easement and resources, and management responsibilities.
- **Section 5.6 FERC Jurisdiction:** addresses one of the goals of the approved study plan by clarifying FERC jurisdiction.

The materials in this report comprise Boott's understanding of ownership, easement rights and resource rights to the Lowell canal system based on a review of planning documents, legal documents, and other available information. This report is limited to the documentation available to Boott during the course of the study. Further, this information is not intended to serve as legal or professional advice by Boott and should not be construed as such.

5.1 Conceptual Planning of the Lowell Canal System

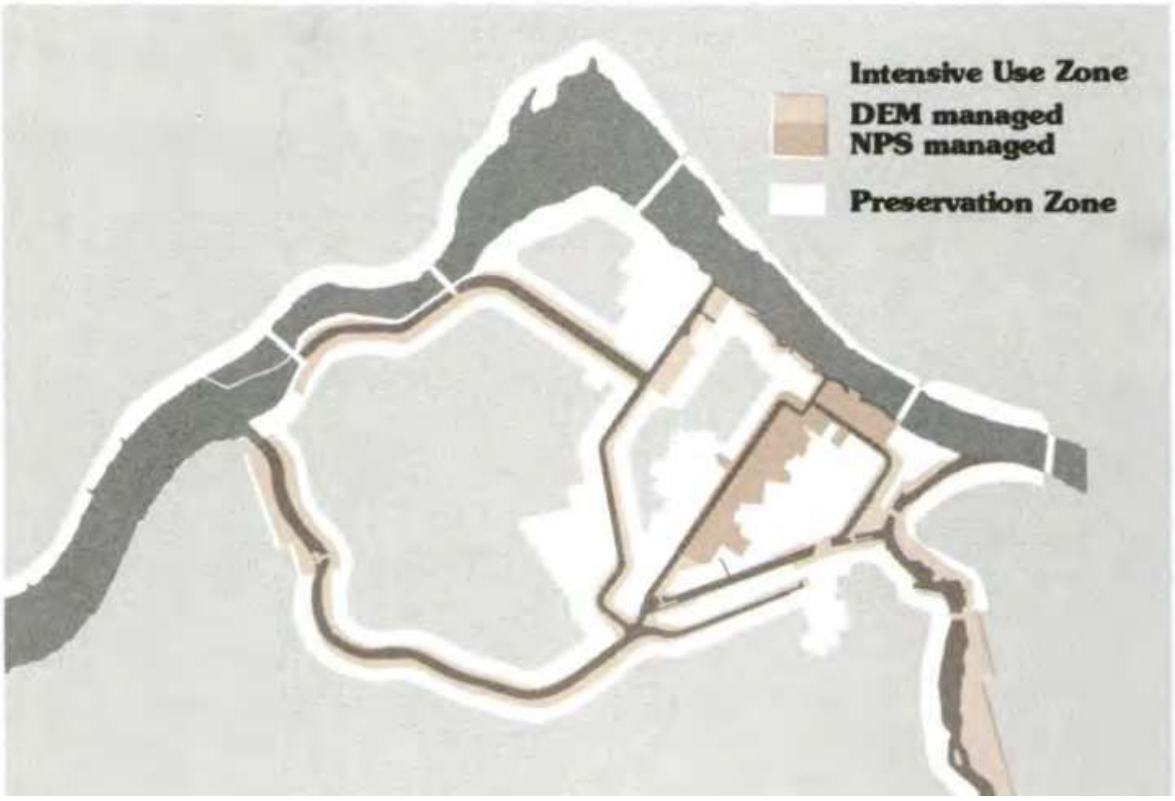
In 1975, the Lowell Historic Canal District Commission (LHCDC) was established by Congress to prepare a plan for the preservation and interpretation of Lowell's historic resources in and around the Lowell canal system. The *1977 Report of the LHCDC* (commonly referred to as the "Brown Book") produced the legislation that was passed by Congress in 1978 and signed into law by President Carter. This law established a two-tiered federal involvement: the LNHP acting as a unit of the NPS, and the Lowell Historic Preservation District (LHPD or the District)—administered by a commission under the Department of the Interior.

The *1977 Report of the LHCDC* proposed the creation of LNHP and presented the approach to developing the Lowell canal system and surrounding areas as a national park. The LHCDC stated that the key to development of the LNHP was a cooperative undertaking of the NPS and the Massachusetts Department of Environmental Management, the agency now known as MADCR. This partnership would "share state and federal resources, maximizing the effectiveness and abilities of each." Given the dense urban setting, it was understood that almost all the structures would remain in private ownership, but the structures would be developed and managed by NPS and MADCR (NHCDC 1977, p. 46). The authors further elaborated that "the NPS would develop an overall interpretive program and restore certain buildings and settings. The State would preserve the canal system and develop its recreational potentials." The specific responsibilities of each agency as identified in the *1977 Report of the LHCDC* are outlined below in Table 5-1 and Figure 5-1.

Table 5-1. Agency Responsibilities Identified in 1977 Report of the LHCDC

Agency	Responsibilities
NPS	interpretation, park wide downtown "cross-section" of 19th Century Lowell (including preservation, building and open space improvements, transportation and visitor services)
MADCR	canals, riverbanks, and related recreational areas gatehouses, locks and dams barge system

Figure 5-1. LNHP Management Responsibility Zones



Within the intensive use zone, both NPS and MADCR were tasked with acquiring and improving property, as well as developing and operating the major visitor attractions in the LNHP. The costs of park development, management, and maintenance would be shared on a *pro rata* basis between NPS and MADCR (LHCDC 1977). Additionally, the plan elaborated on the supportive involvement of local government, whose efforts in preservation in the downtown and elsewhere would dovetail in the LNHP.

In 1980, the *Preservation Plan* and *Details of the Preservation Plan* were published by the LHPC (LHPC 1980a; LHPC 1980b). *Details of the Preservation Plan* specified the roles of NPS, the Commonwealth of Massachusetts (acting through MADCR), and the City of Lowell. LNHP was to rehabilitate certain gatehouses and perform exterior façade improvements, among other tasks. MADCR's role was to acquire all or portions of the Lowell canal system, including the interpretive and recreational water access rights, and "also undertake the landscaping, repair and maintenance of all the basic canal structural components, canal related structures and canal related land for recreational use." The City of Lowell was to implement certain downtown street and pedestrian improvements, such as exposures of cobblestone streets, bricking, and paving of sidewalks.

In August 1981, NPS developed and issued the FGMP to provide a basis for visitor use, resource management, and general development within the LNHP. The FGMP states management of the Lowell canal system will be accomplished through cooperative agreements between private and public entities, but MADCR is the lead agency

responsible for maintaining, developing, and renovating the major elements of the canal system (NPS 1981). Proprietors, the owner of most of the Lowell canal system at the time, was responsible for the maintenance and operation of the hydromechanical components.

The Preservation Plan Amendment was released in 1990 (LHPC 1990). This plan presented NPS and MADCR as the lead parties responsible for preservation and maintenance of the Lowell canal system. The report stated that "Boott uses canal water to generate hydropower and performs all maintenance tasks directly related to that end. This includes keeping up machinery like control gates and turbines located at various points along the system." The *Preservation Plan Amendment* acknowledged that MADCR has the right to maintain and repair canal walls.

The conceptual framework for the rights and responsibilities for management of the Lowell canal system remain consistent within the *1977 Report of the LHCDC*, the 1980 *Details of the Preservation Plan*, the 1981 FGMP, and the 1990 *Preservation Plan Amendment*. MADCR and NPS are presented as the main parties responsible for developing, renovating, and maintaining the major elements of the canal system. As discussed in the following sections, this collaborative approach to management of the Lowell canal system was solidified with a succession of legal documents exchanging property, easement rights, and resource rights.

5.2 Ownership of the Lowell Canal System

On January 16, 1984, the *Great Deed* was executed between Proprietors, Boott Mills[5], and Boott, and through this deed a considerable portion of the Lowell canal system was conveyed to Boott. Notably, certain portions or resources that were not conveyed to Boott in the 1984 *Great Deed* were later obtained by MADCR through the December 1, 1986 *Order of Taking*, or remain under the legal ownership of Proprietors. Notably, these documents also issued ownership of lands and structures not located within the current FERC Project boundary and therefore outside the scope of this report. The following text describes the ownership of structures within the current FERC Project boundary. The structures discussed below are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.2.1 Pawtucket Dam

According to the 1984 *Great Deed*, the Pawtucket Dam is owned by Boott in its entirety and any and all equipment and mechanisms located in or on said dam or appurtenant thereto including fishways (Appendix B, p. 2).

5.2.2 Pawtucket Canal

According to the 1984 *Great Deed* and the 1986 *Order of Taking*, the length of the Pawtucket Canal and Lower Pawtucket Canal are currently owned by the Proprietors, including the canal walls (to the exterior planes), beds, and bottoms (Appendix B, p. 2, 4-5). As described below, structures and fixtures within the Pawtucket Canal have mixed ownership, with certain structures being jointly or independently owned by Proprietors and MADCR. Boott is not known to have legal ownership of any structures of or within the Pawtucket Canal. The boundaries of ownership of the Pawtucket Canal structures discussed below are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.2.2.1 Francis Gatehouse

The Francis Gatehouse, also known as the Great Gate Gatehouse, is owned in part by MADCR and Proprietors. It is part of the Guard Lock and Gates facility and houses the Great Guard Gate. Proprietors owns all buildings, structures, and fixtures of the Francis Gatehouse below an elevation of 106.2 ft Mean Sea Level (MSL). MADCR owns all buildings, structures, and fixtures associated with the Francis Gatehouse above 106.2 ft MSL, with the exception of fixtures and equipment used in the ongoing maintenance and operation of hydroelectric power generation. The fixtures and equipment of the Francis

[5] Boott Mills was organized in the State of Massachusetts on May 29, 1964 and was the original co-Licensee of the Project with Proprietors. Boott Mills operated the downtown mill powerhouses before the Project was transferred to Boott in December 1984.

Gatehouse used in the ongoing maintenance and operation of hydroelectric power generation above 106.2 ft MSL are owned by Proprietors (Appendix C, p. 20; Appendix B, p. 2, 4-5).

5.2.2.2 Hydraulic Gatehouse

The Hydraulic Gatehouse, also known as the Guard Locks Gatehouse, is owned in part by MADCR and Proprietors. It is also part of the Guard Lock and Gates facility and houses the five headgates which control flow into the Pawtucket Canal. Proprietors owns all buildings, structures, and fixtures of the Hydraulic Gatehouse below an elevation of 88.2 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Hydraulic Gatehouse above 88.2 ft MSL, with the exception of fixtures and equipment used in the ongoing maintenance and operation of hydroelectric power generation. The fixtures and equipment of the Hydraulic Gatehouse used for ongoing maintenance and operation of hydroelectric power generation above 88.2 ft MSL are owned by Proprietors. (Appendix C, p. 20; Appendix B, p. 2, 4-5).

5.2.2.3 Guard Locks Locking Gatehouse

The Guard Locks Locking Gatehouse is owned in part by MADCR and Proprietors. It is also part of the Guard Lock and Gates facility. Proprietors owns all structures and fixtures of the Guard Locks Locking Gatehouse below an elevation of 99.2 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Pawtucket Gatehouse above 99.2 ft MSL, with the exception of fixtures and equipment used in the ongoing maintenance and operation of hydroelectric power generation. The fixtures and equipment of the Guard Locks Locking Gatehouse used for ongoing maintenance and operation of hydroelectric power generation above 99.2 ft MSL are owned by Proprietors. (Appendix C, p. 21; Appendix B, p. 2, 4-5).

5.2.2.4 Guard Locks Lock Chambers

The Guard Locks Lock Chambers, also known as the Lower Locking Gate, are owned by Proprietors (Appendix C, p. 21; Appendix B, p. 2, 4-5).

5.2.2.5 Swamp Locks Gatehouse

The Swamp Locks Gatehouse is owned in part by MADCR and Proprietors. Proprietors owns all structures and fixtures of the Swamp Locks Gatehouse below an elevation of 89.2 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Swamp Locks Gatehouse above 89.2 ft MSL, with the exception of fixtures and equipment used in the ongoing maintenance and operation of hydroelectric power generation. The fixtures and equipment of the Swamp Locks Gatehouse used for ongoing maintenance and operation of hydroelectric power generation above 89.2 ft MSL are owned by Proprietors. (Appendix C, p. 16; Appendix B, p. 2, 4-5).

5.2.2.6 Swamp Locks Dam (North)

The Swamp Locks Dam (North) is owned in its entirety by the Proprietors (Appendix B, p. 2, 5). The Pawtucket Canal, and thus structures within the Pawtucket Canal, were not conveyed to Boott from Proprietors in the 1984 *Great Deed*. Similarly, MADCR did not acquire legal ownership of the Swamp Locks Dam (North) in the 1986 *Order of Taking* (Appendix C, p. 16-17).

5.2.2.7 Swamp Locks Dam (South)

The Swamp Locks Dam (South) is owned in its entirety by the Proprietors (Appendix B, p. 2, 5). The Pawtucket Canal, and thus structures within the Pawtucket Canal, were not conveyed to Boott from Proprietors in the 1984 *Great Deed*. Similarly, MADCR did not acquire legal ownership of the Swamp Locks Dam (South) in the 1986 *Order of Taking* (Appendix C, p. 17-18).

5.2.2.8 Lower Locks Gatehouse

The Lower Locks Gatehouse is owned in part by MADCR and Proprietors. Proprietors owns all structures and fixtures of the Lower Locks Gatehouse below an elevation of 74.2 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Lower Locks Gatehouse above 74.2 ft MSL, with the exception of structures and equipment used in the ongoing maintenance and operation of hydroelectric power generation. The fixtures and equipment of the Lower Locks Gatehouse used for ongoing maintenance and operation of hydroelectric power generation above 74.2 ft MSL are owned by Proprietors (Appendix C, p. 24; Appendix B, p. 2, 4-5).

5.2.2.9 Lower Locks Lock Chamber

The Lower Locks Lock Chamber is owned in its entirety by the Proprietors (Appendix B, p. 2, 5). The Pawtucket Canal, and thus structures within the Pawtucket Canal, were not conveyed to Boott from Proprietors in 1984. Similarly, MADCR did not acquire ownership of the Lower Locks Lock Chamber in the 1986 *Order of Taking* (Appendix C, p. 24-25).

5.2.2.10 Lower Locks Dam

The Lower Locks Dam is owned in its entirety by the Proprietors (Appendix B, p. 2, 5). The Pawtucket Canal, and thus structures within the Pawtucket Canal, were not conveyed to Boott from Proprietors in 1984. Similarly, MADCR did not acquire ownership of the Lower Locks Dam in the 1986 *Order of Taking* (Appendix C, p. 24-25).

5.2.2.11 Assets Power Station

Hydropower and generating equipment associated with Assets Power Station is owned by Boott, including all turbines, generators, governors, exciters, control panels, main

breakers, and transformers, transmission lines, and related mechanisms necessary for the production and transmission of electricity (Appendix B, p. 8). Turbine rooms and mill buildings or structures associated with Assets Power Station were excluded from this review as they are located outside of the FERC Project Boundary.

The penstock feeding the units of Assets Power Station is owned by Proprietors (Appendix B, p. 8).

The tailrace from Assets Power Station discharging into the Pawtucket Canal is owned by Proprietors (Appendix B, p. 8).

5.2.3 Northern Canal

The Northern Canal was conveyed from Proprietors to Boott in the 1984 *Great Deed*. The Northern Canal was conveyed to the exterior plane of the canal walls, and includes all sluiceways, dams, and gates, except otherwise noted below (Appendix B, p. 2-3). Structures and fixtures within the Northern Canal have mixed ownership, with certain structures being jointly or independently owned by Proprietors, Boott, and MADCR. The boundaries of ownership of the Northern Canal structures discussed below are depicted in Appendix A, Appendix E, and the associated GIS database.

5.2.3.1 Pawtucket Gatehouse

The Pawtucket Gatehouse (also known as the Northern Canal Gatehouse) is owned in part by MADCR and Boott. Boott owns all structures and fixtures of the Pawtucket Gatehouse below an elevation of 101.2 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Pawtucket Gatehouse above 101.2 ft MSL, with the exception of any structures needed for ongoing hydroelectric power generation. The fixtures and equipment of the Pawtucket Gatehouse used for ongoing maintenance and operation of hydroelectric power generation above 101.2 ft MSL are owned by Boott. (Appendix C, p. 11; Appendix B, p. 2-3).

5.2.3.2 Pawtucket Gatehouse Lock Chamber

The Pawtucket Gatehouse Lock Chamber above an elevation of 82.7 ft MSL was expressly reserved from conveyance to Boott in the 1984 *Great Deed* (Appendix B, p. 3), and remains under the legal ownership of Proprietors.

5.2.3.3 Northern Canal Waste Gatehouse

The Northern Canal Waste Gatehouse is owned in part by Proprietors and MADCR. The Northern Canal Waste Gatehouse was expressly reserved (without limitation) from conveyance to Boott in the 1984 *Great Deed* (Appendix B, p. 5). In the 1986 *Order of Taking*, MADCR obtained ownership of all buildings, structures, and fixtures associated with the Northern Canal Waste Gatehouse above 92.2 ft MSL, with the exception of any fixtures and equipment used in the ongoing maintenance and operation of hydroelectric

power generation (Appendix C, p. 15). The fixtures and equipment of the Northern Canal Waste Gatehouse used for ongoing maintenance and operation above 92.2 ft MSL are owned by Proprietors.

5.2.3.4 HydroLocks

The lock and control structure located at the bend of the Northern Canal was constructed by and is owned by Boott.

5.2.3.5 Great River Wall

The Great River Wall was expressly reserved from conveyance to Boott in the 1984 *Great Deed*, and remains under the legal ownership of Proprietors. The Great River Wall is the left retaining wall of the Northern Canal. It runs 2,485 feet from the Pawtucket Gatehouse to a natural rock outcrop upstream of the E.L. Field Powerhouse (Appendix B, p. 5; Appendix C, p. 13-15).

5.2.3.6 Northern Canal Walkway

The Northern Canal Walkway runs atop the Great River Wall for most of its length. The portion of the Northern Canal Walkway atop the Great River Wall is owned by Proprietors as a part of the Great River Wall. The westmost portion of the Northern Canal Walkway that diverts off the Great River Wall and extends into the Northern Canal Island (Parcel 29-B in Appendix A) is owned by MADCR.

5.2.4 Western Canal

The Western Canal was conveyed from Proprietors to Boott in the 1984 *Great Deed*, including the lower portion also known as the Lawrence Canal. The Western Canal was conveyed in its entirety to the exterior plane of the canal walls, and includes all sluiceways, dams, and gates, except those otherwise noted below (Appendix B, p. 2-3). Structures and fixtures within the Western Canal have mixed ownership, with certain structures being jointly or independently owned by Boott and MADCR. The boundaries of ownership of the Western Canal structures discussed below are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.2.4.1 Tremont Gatehouse

The Tremont Gatehouse is owned in part by Boott and MADCR. Boott owns all structures and fixtures of the Tremont Gatehouse below an elevation of 90.2 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Tremont Gatehouse above 90.2 ft MSL, with the exception of fixtures and structures needed for ongoing maintenance and operation of hydroelectric power generation. The structures and equipment of the Tremont Gatehouse used for ongoing maintenance and operation of

hydroelectric power generation above 90.2 ft MSL are owned by Boott. (Appendix C, p. 7; Appendix B, p. 2-3).

5.2.4.2 Lawrence Dam

The Lawrence Dam is owned by Boott, and includes all appurtenant equipment or mechanisms, including the headrace, tailrace, and associated penstocks. Said dam was transferred to Boott by Proprietors with the fee to the underlying land, and all equipment and mechanisms located in or on said dams and gates or appurtenant thereto, including, but not limited to wasteways, penstocks, tailraces, headgates, and racks. (Appendix B, p. 2-3).

5.2.4.3 Hall Street Dam

The Hall Street Dam is owned by Boott, and includes all appurtenant equipment or mechanisms, including the headrace, tailrace, and associated penstocks. Said dam was transferred to Boott by Proprietors with the fee to the underlying land, and all equipment and mechanisms located in or on said dams and gates or appurtenant thereto, including, but not limited to wasteways, penstocks, tailraces, headgates, and racks (Appendix B, p. 2-3).

5.2.5 Merrimack Canal

The Merrimack Canal was conveyed from Proprietors to Boott in the 1984 *Great Deed*. The Merrimack Canal was conveyed in its entirety to the exterior plane of the canal walls, and includes all sluiceways, dams, and gates, except those otherwise noted below (Appendix B, p. 2-3). Structures and fixtures within the Merrimack Canal have mixed ownership, with certain structures being jointly or independently owned by Proprietors, Boott, and MADCR. The boundaries of ownership of the Merrimack Canal structures discussed below are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.2.5.1 Merrimack Gates

The Merrimack Gates are owned by Boott and includes all appurtenant equipment or mechanisms. Said gates were transferred to Boott by Proprietors with the fee to the underlying land, and all equipment and mechanisms located in or on said gates or appurtenant thereto, including, but not limited to wasteways, penstocks, tailraces, headgates, and racks. (Appendix B, p. 2-3).

5.2.5.2 YMCA Gates

The YMCA Gates are owned by Boott, and includes all appurtenant equipment or mechanisms (Appendix B, p. 2-3).

5.2.5.3 Moody Street Feeder Gatehouse

The Moody Street Feeder Gatehouse is owned in part by NPS and Boott. Structures of the Moody Street Feeder Gatehouse above an elevation of 92.2 ft MSL were expressly reserved from conveyance in the 1984 *Great Deed* (Appendix B, p. 3). In July 2001, NPS purchased Moody Street Feeder Gatehouse (above an elevation of 92.2 ft MSL) from Proprietors. Boott owns all structures and fixtures of the Moody Street Feeder Gatehouse below an elevation of 92.2 ft MSL. The structures and equipment of the Moody Street Feeder Gatehouse used for ongoing maintenance and operation of hydroelectric power are owned by Boott (Appendix B, p. 2-3).

5.2.5.4 Moody Street Feeder

The Moody Street Feeder is owned by Boott, and includes all appurtenant equipment or mechanisms, including the headrace, tailrace, and associated penstocks (Appendix B, p. 2-3).

5.2.6 Eastern Canal

The Eastern Canal was conveyed from Proprietors to Boott in the 1984 *Great Deed*. The Eastern Canal was conveyed in its entirety to the exterior plane of the canal walls, and includes all sluiceways, dams, and gates, except those otherwise noted below (Appendix B, p. 2-3). Structures and fixtures within the Eastern Canal have mixed ownership, with certain structures being jointly or independently owned by Boott and MADCR. The boundaries of ownership of the Eastern Canal structures discussed below are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.2.6.1 Massachusetts Wasteway Gatehouse

The Massachusetts Wasteway Gatehouse is owned in part by Boott and MADCR. Boott owns all structures and fixtures of the Massachusetts Wasteway Gatehouse below an elevation of 80.2 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Massachusetts Wasteway Gatehouse above 80.2 ft MSL, with the exception of fixtures and structures needed for ongoing maintenance and operation of hydroelectric power generation. The structures and equipment of the Massachusetts Wasteway Gatehouse used for ongoing maintenance and operation of hydroelectric power generation above 80.2 ft MSL are owned by Boott (Appendix C, p. 7; Appendix B, p. 2-3).

5.2.6.2 Boott Dam Gatehouse

The Boott Dam Gatehouse is owned in part by Boott and MADCR. Boott owns all structures and fixtures of the Boott Dam Gatehouse below an elevation of 74.2 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Boott Dam Gatehouse above 74.2 ft MSL, with the exception of fixtures and structures needed for ongoing maintenance and operation of hydroelectric power generation. The structures

and equipment of the Boott Dam Gatehouse used for ongoing maintenance and operation of hydroelectric power generation above 74.2 ft MSL are owned by Boott. (Appendix C, p. 7; Appendix B, p. 2-3).

5.2.6.3 Boott Dam

The Boott Dam is owned by Boott, and includes all appurtenant equipment or mechanisms, including the headrace, tailrace, and associated penstocks. Said dam was transferred to Boott by Proprietors with the fee to the underlying land, and all equipment and mechanisms located in or on said dams and gates or appurtenant thereto, including, but not limited to wasteways, penstocks, tailraces, headgates, and racks (Appendix B, p. 2-3).

5.2.6.4 Rolling Dam Gatehouse (North)

The Rolling Dam Gatehouse (North) is owned in part by Boott and MADCR. Boott owns all structures and fixtures of the Rolling Dam Gatehouse (North) below an elevation of 83.7 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Rolling Dam Gatehouse (North) above 83.7 ft MSL, with the exception of fixtures and structures needed for ongoing maintenance and operation of hydroelectric power generation. The structures and equipment of the Rolling Dam Gatehouse (North) used for ongoing maintenance and operation of hydroelectric power generation above 83.7 ft MSL are owned by Boott (Appendix C, p. 29; Appendix B, p. 2-3).

5.2.6.5 Rolling Dam Gatehouse (South)

The Rolling Dam Gatehouse (South) is owned in part by Boott and MADCR. Boott owns all structures and fixtures of the Rolling Dam Gatehouse (South) below an elevation of 83.7 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Rolling Dam Gatehouse (South) above 83.7 ft MSL, with the exception of fixtures and structures needed for ongoing maintenance and operation of hydroelectric power generation. The structures and equipment of the Rolling Dam Gatehouse (South) used for ongoing maintenance and operation of hydroelectric power generation 83.7 ft MSL are owned by Boott (Appendix C, p. 29; Appendix B, p. 2-3).

5.2.6.6 Rolling Dam

The Rolling Dam is owned by Boott, and includes all appurtenant equipment or mechanisms, including the headrace, tailrace, and associated penstocks (Appendix B, p. 2-3). Said dam was transferred to Boott by Proprietors with the fee to the underlying land, and all equipment and mechanisms located in or on said dams and gates or appurtenant thereto, including, but not limited to wasteways, penstocks, tailraces, headgates, and racks.

5.2.6.7 Boott Penstock

The Boott Penstock from the Eastern Canal to the Merrimack Canal is owned by MADCR (Appendix C, p. 9).

5.2.6.8 Merrimack Dam

The Merrimack Dam is owned by Boott, and includes all appurtenant equipment or mechanisms, including the headrace, tailrace, and associated penstocks (Appendix B, p. 2-3).

5.2.6.9 John Street Power Station

Hydropower and generating equipment associated with John Street Power Station is owned by Boott, including all turbines, generators, governors, exciters, control panels, main breakers, and transformers, transmission lines, and related mechanisms necessary for the production and transmission of electricity (Appendix B, p. 8). Turbine rooms and mill buildings or structures associated with John Street Power Station were excluded from this review as they are located outside of the FERC Project Boundary.

The penstocks feeding the units of John Street Power Station are owned by Proprietors (Appendix B, p. 8).

The tailrace from John Street Power Station discharging into the Merrimack River is owned by Proprietors (Appendix B, p. 8).

5.2.6.10 Bridge Street Power Station

Hydropower and generating equipment associated with Bridge Street Power Station (Section 8) is owned by Boott, including all turbines, generators, governors, exciters, control panels, main breakers, and transformers, transmission lines, and related mechanisms necessary for the production and transmission of electricity (Appendix B, p. 8). Turbine rooms and mill buildings or structures associated with Bridge Street Power Station were excluded from this review as they are located outside of the FERC Project Boundary.

The penstocks feeding the units of Bridge Street Power Station are owned by Proprietors (Appendix B, p. 8).

The tailrace from Bridge Street Power Station discharging into the Concord River is owned by Proprietors (Appendix B, p. 8).

5.2.7 Hamilton Canal

The Hamilton Canal was conveyed from Proprietors to Boott in the 1984 *Great Deed*. The Hamilton Canal was conveyed in its entirety to the exterior plane of the canal walls,

and includes all sluiceways, dams, and gates, except those otherwise noted below (Appendix B, p. 2-3). Structures and fixtures within the Hamilton Canal have mixed ownership, with certain structures being jointly or independently owned by Boott and MADCR. The boundaries of ownership of the Hamilton Canal structures discussed below are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.2.7.1 Hamilton Gatehouse

The Hamilton Gatehouse is owned in part by Boott and MADCR. Boott owns all structures and fixtures of the Hamilton Gatehouse below an elevation of 90.2 ft MSL. MADCR owns buildings, structures, and fixtures associated with the Hamilton Gatehouse above 90.2 ft MSL, with the exception of fixtures and structures needed for ongoing maintenance and operation of hydroelectric power generation. The structures and equipment of the Hamilton Gatehouse used for ongoing maintenance and operation of hydroelectric power generation above 90.2 ft MSL are owned by Boott (Appendix C, p. 9; Appendix B, p. 2-3).

5.2.7.2 Hamilton Power Station

Hydropower and generating equipment associated with Hamilton Power Station is owned by Boott, including all turbines, generators, governors, exciters, control panels, main breakers, and transformers, transmission lines, and related mechanisms necessary for the production and transmission of electricity (Appendix B, p. 8). Turbine rooms and mill buildings or structures associated with Hamilton Power Station were excluded from this review as they are located outside of the FERC Project Boundary.

The penstocks feeding the units of Hamilton Power Station are owned by Proprietors (Appendix B, p. 8).

The tailrace from Bridge Street Power Station discharging into the Pawtucket Canal is owned by Proprietors (Appendix B, p. 8).

5.3 Easement Rights to the Lowell Canal System

On January 16, 1984, the *Great Deed* was executed between Proprietors, Boott Mills, and Boott, and through this deed various easement rights were conveyed to Boott. Additionally, MADCR later obtained easement rights to the canal system through the December 1, 1986 *Order of Taking*, and NPS obtained easement rights in the 1995 *Grant of Easement*. The following text describes the easement rights to the structures within the canal system based on an analysis of the 1984 *Great Deed*, the 1986 *Order of Taking*, and the 1995 *Grant of Easement*. Notably, these three documents issued easements and rights that are not associated with lands and structures located within the current FERC Project boundary, therefore these are excluded from discussion in this report. The structures discussed below are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.3.1 Pawtucket Canal

The 1984 *Great Deed* conveyed to Boott an easement to the Pawtucket Canal and Lower Pawtucket Canal. This easement was granted in common with Proprietors for the right to install conduits, pipes, and wiring, and the right to maintain, repair and replace the canal walls (Appendix B, p. 4-5).

In the 1986 *Order of Taking*, MADCR acquired a permanent and exclusive easement to all Pawtucket and Lower Pawtucket Canal walls, beds or bottoms, and to all dams and lock chambers located in the canals, for the following purposes (Appendix C, p. 33):

a) Support of all fixtures or structures of the Commonwealth now or hereafter attached;
b) Preservation and conservation;
c) Supplemental maintenance in addition to that performed by the Condemnees (the prior or current owner) and their successors and assigns;
d) Landscaping and erection of exhibits and structures;
e) Placement of barriers and fences;
f) Placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature;
g) Placement of lighting and other utilities;
h) Operation and maintenance of boat locking chambers, if any, for any and all purposes; and
i) Any and all other uses consistent with the operation of the canal system as a park.

The 1995 *Grant of Easement* conveyed to NPS the right to construction and maintenance of improvements, including decking, lighting, benches, and landscaping at various structures and parcels of and around the Pawtucket Canal.

As understood based on a review of the described documents, MADCR has permanent and exclusive rights to all Pawtucket Canal walls, beds or bottoms for purposes a-i listed

above. The expressed exclusivity of this easement indicates that MADCR's rights to implement any of those purposes at or in the Pawtucket Canal precede the rights of all other parties. Boott and Proprietors have the right, in common with each other, to install conduits, pipes, and wiring, and to maintain, repair, and replace the Pawtucket Canal walls. Additionally, through the 1995 *Grant of Easement*, MADCR conveyed to NPS easement rights at various structures and parcels of the Pawtucket Canal.

As described below, structures and fixtures within the Pawtucket Canal have mixed easement rights, with certain structures sharing similar rights among different parties. The boundaries of easements to structures are assumed to follow the boundaries of ownership, which are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.3.1.1 Francis Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Francis Gatehouse. Said easement consists of the exclusive right of operation and controlling the Francis Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Francis Gatehouse. In common with Proprietors and others entitled, Boott has the right to access Francis Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Pawtucket Canal walls, beds or bottoms for support of the Francis Gatehouse, structures, and fixtures, as well as the right to access the Francis Gatehouse (Appendix C, p. 20).

The 1995 *Grant of Easement* granted NPS the right for construction and maintenance of improvements such as walkway surfaces, lighting, railings, decking benches, and landscaping, and any other uses consistent with park uses (Appendix D, p. 2).

5.3.1.2 Hydraulic Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Hydraulic Gatehouse. Said easement consists of the exclusive right of operation and controlling the Hydraulic Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Hydraulic Gatehouse. In common with Proprietors and others entitled, Boott has the right to access Hydraulic Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Pawtucket Canal walls, beds or bottoms for support of the Hydraulic Gatehouse, structures, and fixtures, as well as the right to access the Hydraulic Gatehouse (Appendix C, p. 20).

The 1995 *Grant of Easement* granted NPS the right for construction and maintenance of improvements such as walkway surfaces, lighting, railings, decking benches, and landscaping, and any other uses consistent with park uses (Appendix D, p. 2).

5.3.1.3 Guard Locks Locking Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Guard Locks Locking Gatehouse. Said easement consists of the exclusive right of operation and controlling the Guard Locks Locking Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Guard Locks Locking Gatehouse. In common with Proprietors and others entitled, Boott has the right to access Guard Locks Locking Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1995 *Grant of Easement* granted NPS the right for construction and maintenance of improvements such as walkway surfaces, lighting, railings, decking benches, and landscaping, and any other uses consistent with park uses (Appendix D, p. 2).

5.3.1.4 Guard Locks Lock Chambers

MADCR has permanent and exclusive rights to the Guard Locks Lock Chambers for purposes a-i listed above in Section 5.3.1.

5.3.1.5 Swamp Locks Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Swamp Locks Gatehouse. Said easement consists of the exclusive right of operation and controlling the Swamp Locks Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Swamp Locks Gatehouse. In common with Proprietors and others entitled, Boott has the right to access Swamp Locks Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Pawtucket Canal walls, beds or bottoms for support of the Swamp Locks Gatehouse, structures, and fixtures, as well as the right to access the Swamp Locks Gatehouse (Appendix C, p. 16).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Swamp Lock Gatehouse (Appendix D, p. 3).

5.3.1.6 Swamp Locks Dam (North)

As understood based on a review of the described documents, Boott has the rights, in common with Proprietors, to install conduits, pipes, and wiring. Boott has the right to maintain and operate Swamp Locks Dam (North) (Appendix B, p. 4-5).

Additionally, MADCR has permanent and exclusive easement rights to Swamp Locks Dam (North) and all Pawtucket Canal walls, beds or bottoms for purposes a-i listed above in Section 5.3.1, provided those purposes do not interfere with Boott's use of the structure for hydroelectric power generation. The expressed exclusivity of this easement indicates that MADCR's rights to implement any of those purposes at Swamp Locks Dam (North) precede the rights of all other parties, including the land and/or property owner. All other property rights not mentioned reside with Proprietors, the present owner of the Pawtucket Canal and Swamp Locks Dam (North) (Appendix C, p. 16-17; Appendix B, p. 2, 4-5).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Swamp Locks Dam (North) (Appendix D, p. 3).

5.3.1.7 Swamp Locks Dam (South)

As understood based on a review of the described documents, Boott has the rights, in common with Proprietors, for the uninterrupted flowage of water past Swamp Locks Dam (South), as well as the rights to install conduits, pipes, and wiring. Boott has the right to maintain and operate Swamp Locks Dam (South) (Appendix B, p. 4-5).

Additionally, MADCR has permanent and exclusive easement rights to Swamp Locks Dam (South) and all Pawtucket Canal walls, beds or bottoms for purposes a-i listed above in Section 5.3.1, provided those purposes do not interfere with Boott's use of the structure for hydroelectric power generation. The expressed exclusivity of this easement indicates that MADCR's rights to implement any of those purposes at Swamp Locks Dam (South) precede the rights of all other parties, including the land and/or property owner. All other property rights not mentioned reside with Proprietors, the present owner of the Pawtucket Canal and Swamp Locks Dam (South) (Appendix C, p. 17-18; Appendix B, p. 2, 4-5).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Swamp Locks Dam (South) (Appendix D, p. 3).

5.3.1.8 Lower Locks Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Lower Locks Gatehouse. Said easement consists of the exclusive right of operation and controlling the Lower Locks Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Lower Locks Gatehouse. In common with Proprietors and others entitled, Boott has the right to access Lower Locks Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Pawtucket Canal walls, beds or bottoms for support of the Lower Locks Gatehouse, structures, and fixtures, as well as the right to access the Lower Locks Gatehouse (Appendix C, p. 16).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Lower Locks Gatehouse (Appendix D, p. 3).

5.3.1.9 Lower Locks Lock Chamber

MADCR has permanent and exclusive rights to the Lower Locks Lock Chamber for purposes a-i listed above in Section 5.3.1.

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Lower Locks Lock Chamber (Appendix D, p. 3).

5.3.1.10 Lower Locks Dam

As understood based on a review of the described documents, Boott has the rights, in common with Proprietors, to install conduits, pipes, and wiring. Boott has the right, in common with Proprietors, to maintain and operate Lower Locks Dam (Appendix B, p. 4-5).

Additionally, MADCR has permanent and exclusive easement rights to Lower Locks Dam and all Pawtucket Canal walls, beds or bottoms for purposes a-i listed above in Section 5.3.1, provided those purposes do not interfere with Boott's use of the structure for hydroelectric power generation. The expressed exclusivity of this easement indicates that MADCR's rights to implement any of those purposes at Lower Locks Dam precede the rights of all other parties, including the land and/or property owner. All other property rights not mentioned reside with Proprietors, the present owner of the Pawtucket Canal and Lower Locks Dam (Appendix C, p. 24-25; Appendix B, p. 2, 4-5).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Lower Locks Dam (Appendix D, p. 3).

5.3.1.11 Assets Power Station

In the 1984 *Great Deed,* Boott obtained an easement to operate, maintain, repair and replace the existing penstocks leading to the turbines of Assets Power Station from the Merrimack Canal, and to remove any such penstock in order to replace it with a penstock of the same or a different size and construction (Appendix B, p. 8).

Boott also obtained an easement to operate, maintain, repair, and replace the existing tailraces leading from the turbines to the Pawtucket Canal, and to remove any such tailrace in order to replace it with a tailrace of the same or a different size and construction (Appendix B, p. 8).

5.3.2 Northern Canal

In the 1986 *Order of Taking*, MADCR acquired a permanent and exclusive easement to all canal walls, beds or bottoms, and to all dams and lock chambers located in the Northern Canal for the following purposes (Appendix C, p. 33):

a) Support of all fixtures or structures of the Commonwealth now or hereafter attached;
b) Preservation and conservation;
c) Supplemental maintenance in addition to that performed by the Condemnees (the prior or current owner) and their successors and assigns;
d) Landscaping and erection of exhibits and structures;
e) Placement of barriers and fences;
f) Placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature;
g) Placement of lighting and other utilities;
h) Operation and maintenance of boat locking chambers, if any, for any and all purposes; and
i) Any and all other uses consistent with the operation of the canal system as a park.

The 1995 *Grant of Easement* conveyed to NPS the right to construct and maintain improvements, including decking, lighting, benches, and landscaping at various structures and parcels of and around the Northern Canal.

As understood based on a review of the described documents, MADCR has permanent and exclusive rights to all Northern Canal walls, beds or bottoms for purposes a-i listed above. The expressed exclusivity of this easement indicates that MADCR's rights to implement any of those purposes at or in the Northern Canal precede the rights of all other parties. Additionally, through the 1995 *Grant of Easement*, MADCR conveyed to NPS easement rights at various structures and parcels of the Northern Canal.

As described below, structures and fixtures within the Northern Canal have mixed easement rights, with certain structures sharing similar rights among different parties. The boundaries of easements to structures are assumed to follow the boundaries of ownership, which are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.3.2.1 Pawtucket Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Pawtucket Gatehouse. Said easement consists of the exclusive right of operation and controlling the Pawtucket Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Pawtucket Gatehouse. Boott has the right to access Pawtucket Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Northern Canal walls, beds or bottoms for support of the Pawtucket Gatehouse, structures, and fixtures, as well as the right to access the Pawtucket Gatehouse (Appendix C, p. 16). MADCR also obtained an exclusive and permanent easement to the Pawtucket Gatehouse Wall and Lock Chamber for purposes a-i listed above in Section 5.3.2, provided that such activities do not interfere with Boott's hydroelectric power production.

5.3.2.2 Pawtucket Gatehouse Lock Chamber

In the 1986 *Order of Taking*, MADCR acquired a permanent and exclusive easement to the Pawtucket Gatehouse Lock Chamber for purposes a-i listed above in Section 5.3.2, provided that such activities do not interfere with Boott's hydroelectric power production.

The 1995 *Grant of Easement* granted NPS the right for construction and maintenance of improvements of the Pawtucket Gatehouse Lock Chamber (Appendix D, p. 2).

5.3.2.3 Northern Canal Waste Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Northern Canal Waste Gatehouse. Said easement consists of the exclusive right of operation and controlling the Northern Canal Waste Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Northern Canal Waste Gatehouse. Boott has the right to access Northern Canal Waste Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Northern Canal walls, beds or bottoms for support of the Northern Canal Waste Gatehouse, structures, and fixtures, as well as the right to access the Northern Canal Waste Gatehouse (Appendix C, p. 15).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Northern Canal Waste Gatehouse (Appendix D, p. 3).

5.3.2.4 Great River Wall

The 1984 *Great Deed* conveyed to Boott an easement for the right to maintain real and personal property of the Great River Wall. Said easement consists of the exclusive right of operation and controlling the Great River Wall, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms of the Great River Wall. Boott, in common with Proprietors, has the right to access Great River Wall for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent and exclusive easement in the Northern Canal walls, beds or bottoms, to implement any of the purposes a-i listed above in Section 5.3.2.

NPS has secured easements for improvements to the walkway and installation of railings and ramps, and rights acquired include a right to install, maintain or remove boat docking, railings, fencing, curbing, paving, lighting, landscaping, signs, walkway; and a right to access for above.

5.3.2.5 Northern Canal Walkway

The 1986 *Order of Taking* conveyed to MADCR a permanent and exclusive easement to the Northern Canal Walkway to implement any of the purposes a-i listed above in Section 5.3.2.

NPS has secured easements for improvements to the walkway and installation of railings and ramps, and rights acquired include a right to install, maintain or remove boat docking, railings, fencing, curbing, paving, lighting, landscaping, signs, walkway; and a right to access for above.

5.3.3 Western Canal

In the 1986 *Order of Taking*, MADCR acquired a permanent and exclusive easement to all canal walls, beds or bottoms, and to all dams and lock chambers located in the Western Canal for the following purposes (Appendix C, p. 33):

a) Support of all fixtures or structures of the Commonwealth now or hereafter attached;
b) Preservation and conservation;
c) Supplemental maintenance in addition to that performed by the Condemnees (the prior or current owner) and their successors and assigns;
d) Landscaping and erection of exhibits and structures;
e) Placement of barriers and fences;
f) Placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature;
g) Placement of lighting and other utilities;
h) Operation and maintenance of boat locking chambers, if any, for any and all purposes; and
i) Any and all other uses consistent with the operation of the canal system as a park.

The 1995 *Grant of Easement* conveyed to NPS the right to construction and maintenance of improvements, including decking, lighting, benches, and landscaping at various structures and parcels of and around the Western Canal.

As understood based on a review of the described documents, MADCR has permanent and exclusive rights to all Western Canal walls, beds or bottoms for purposes a-i listed above. The expressed exclusivity of this easement indicates that MADCR's rights to implement any of those purposes at or in the Western Canal precede the rights of all other parties. Additionally, through the 1995 *Grant of Easement*, MADCR conveyed to NPS easement rights at various structures and parcels of the Western Canal.

As described below, structures and fixtures within the Western Canal have mixed easement rights, with certain structures sharing similar rights among different parties. The boundaries of easements to structures are assumed to follow the boundaries of ownership, which are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.3.3.1 Tremont Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Tremont Gatehouse. Said easement consists of the exclusive right of operation and controlling the Tremont Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Tremont Gatehouse. Boott has the right to access Tremont Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Western Canal walls, beds or bottoms for support of the Tremont Gatehouse, structures, and fixtures, as well as the right to access the Tremont Gatehouse (Appendix C, p. 26).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Tremont Gatehouse (Appendix D, p. 3).

5.3.3.2 Lawrence Dam

MADCR obtained an exclusive and permanent easement to the Lawrence Dam for purposes a-i listed above in Section 5.3.3, provided that such activities do not interfere with Boott's hydroelectric power production.

5.3.3.3 Hall Street Dam

MADCR obtained an exclusive and permanent easement to the Hall Street Dam for purposes a-i listed above in Section 5.3.3, provided that such activities do not interfere with Boott's hydroelectric power production.

5.3.4 Merrimack Canal

In the 1986 *Order of Taking*, MADCR acquired a permanent and exclusive easement to all Merrimack Canal walls, beds or bottoms, and to all dams and lock chambers located in the canals, for the following purposes (Appendix C, p. 33):

a) Support of all fixtures or structures of the Commonwealth now or hereafter attached;
b) Preservation and conservation;
c) Supplemental maintenance in addition to that performed by the Condemnees (the prior or current owner) and their successors and assigns;
d) Landscaping and erection of exhibits and structures;
e) Placement of barriers and fences;
f) Placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature;
g) Placement of lighting and other utilities;
h) Operation and maintenance of boat locking chambers, if any, for any and all purposes; and
i) Any and all other uses consistent with the operation of the canal system as a park.

The 1995 *Grant of Easement* conveyed to NPS the right to construction and maintenance of improvements, including decking, lighting, benches, and landscaping at various structures and parcels of and around the Merrimack Canal.

As understood based on a review of the described documents, MADCR has permanent and exclusive rights to all Merrimack Canal walls, beds or bottoms for purposes a-i listed above. The expressed exclusivity of this easement indicates that MADCR's rights to implement any of those purposes at or in the Merrimack Canal precede the rights of all other parties. Additionally, through the 1995 *Grant of Easement*, MADCR conveyed to NPS easement rights at various structures and parcels of the Merrimack Canal.

As described below, structures and fixtures within the Pawtucket Canal have mixed easement rights, with certain structures sharing similar rights among different parties. The boundaries of easements to structures are assumed to follow the boundaries of ownership, which are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.3.4.1 Merrimack Gates

MADCR obtained an exclusive and permanent easement to the Merrimack Gates purposes a-i listed above in Section 5.3.4, provided that such activities do not interfere with Boott's hydroelectric power production.

5.3.4.2 YMCA Gates

MADCR obtained an exclusive and permanent easement to the YMCA Gates purposes a-i listed above in Section 5.3.4, provided that such activities do not interfere with Boott's hydroelectric power production.

5.3.4.3 Moody Street Feeder Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Moody Street Feeder Gatehouse. Said easement consists of the exclusive right of operation and controlling the Moody Street Feeder Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Moody Street Feeder Gatehouse. Boott has the right to access Moody Street Feeder Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

MADCR obtained an exclusive and permanent easement to the Moody Street Feeder Gatehouse for purposes a-i listed above in Section 5.3.4, provided that such activities do not interfere with Boott's hydroelectric power production.

5.3.4.4 Moody Street Feeder

MADCR obtained an exclusive and permanent easement to the Moody Street Feeder for purposes a-i listed above in Section 5.3.4, provided that such activities do not interfere with Boott's hydroelectric power production.

5.3.5 Eastern Canal

In the 1986 *Order of Taking*, MADCR acquired a permanent and exclusive easement to all canal walls, beds or bottoms, and to all dams and lock chambers located in the Eastern Canal for the following purposes (Appendix C, p. 33):

a) Support of all fixtures or structures of the Commonwealth now or hereafter attached;
b) Preservation and conservation;
c) Supplemental maintenance in addition to that performed by the Condemnees (the prior or current owner) and their successors and assigns;
d) Landscaping and erection of exhibits and structures;
e) Placement of barriers and fences;
f) Placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature;
g) Placement of lighting and other utilities;
h) Operation and maintenance of boat locking chambers, if any, for any and all purposes; and
i) Any and all other uses consistent with the operation of the canal system as a park.

As understood based on a review of the described documents, MADCR has permanent and exclusive rights to all Eastern Canal walls, beds or bottoms for purposes a-i listed above. The expressed exclusivity of this easement indicates that MADCR's rights to implement any of those purposes at or in the Eastern Canal precede the rights of all other parties. Additionally, through the 1995 *Grant of Easement*, MADCR conveyed to NPS easement rights at various structures and parcels of the Eastern Canal.

As described below, structures and fixtures within the Eastern Canal have mixed easement rights, with certain structures sharing similar rights among different parties. The boundaries of easements to structures are assumed to follow the boundaries of ownership, which are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.3.5.1 Massachusetts Wasteway Gatehouse

Through the 1986 *Order of Taking*, MADCR obtained a permanent easement in the canal walls, beds, and bottoms for support of the Massachusetts Wasteway Gatehouse, as well as any structures or fixtures of the Massachusetts Wasteway Gatehouse.

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Massachusetts Wasteway Gatehouse (Appendix D, p. 3).

5.3.5.2 Boott Dam Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Boott Dam Gatehouse. Said easement consists of the exclusive right of operation and controlling the Boott Dam Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Boott Dam Gatehouse. Boott has the right to access Boott Dam Gatehouse for repair and

installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Eastern Canal walls, beds or bottoms for support of the Boott Dam Gatehouse, structures, and fixtures, as well as the right to access the Boott Dam Gatehouse (Appendix C, p. 26).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Boott Dam Gatehouse (Appendix D, p. 3).

5.3.5.3 Boott Dam

MADCR obtained an exclusive and permanent easement to the Boott Dam for purposes a-i listed above in Section 5.3.5, provided that such activities do not interfere with Boott's hydroelectric power production.

5.3.5.4 Rolling Dam Gatehouse (North)

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Rolling Dam Gatehouse (North). Said easement consists of the exclusive right of operation and controlling the Rolling Dam Gatehouse (North), and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Rolling Dam Gatehouse (North). Boott has the right to access Rolling Dam Gatehouse (North) for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Eastern Canal walls, beds or bottoms for support of the Rolling Dam Gatehouse (North), structures, and fixtures, as well as the right to access the Rolling Dam Gatehouse (North) (Appendix C, p. 7).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Rolling Dam Gatehouse (North) (Appendix D, p. 3).

5.3.5.5 Rolling Dam Gatehouse (South)

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Rolling Dam Gatehouse (South). Said easement consists of the exclusive right of operation and controlling the Rolling Dam Gatehouse (South), and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Rolling Dam Gatehouse (South). Boott has the right to access

Rolling Dam Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Eastern Canal walls, beds or bottoms for support of the Rolling Dam Gatehouse (South), structures, and fixtures, as well as the right to access the Rolling Dam Gatehouse (South) (Appendix C, p. 7).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Rolling Dam Gatehouse (South) (Appendix D, p. 3).

5.3.5.6 Rolling Dam

MADCR obtained an exclusive and permanent easement to the Rolling Dam for purposes a-i listed above in Section 5.3.5, provided that such activities do not interfere with Boott's hydroelectric power production.

5.3.5.7 Boott Penstock

Boott holds a permanent easement to the Boott Penstock to flow water together with the right to repair and replace said penstock and the right of access (Appendix C, p. 9).

5.3.5.8 Merrimack Dam

MADCR obtained an exclusive and permanent easement to the Merrimack Dam for purposes a-i listed above in Section 5.3.5, provided that such activities do not interfere with Boott's hydroelectric power production.

5.3.5.9 John Street Power Station

In the 1984 *Great Deed,* Boott obtained an easement to operate, maintain, repair and replace the existing penstocks leading to the turbines of John Street Assets Power Station from the Eastern Canal and to remove any such penstock in order to replace it with a penstock of the same or a different size and construction (Appendix B, p. 8).

Boott obtained an easement to operate, maintain, repair, and replace the existing tailraces leading from the turbines to the Merrimack River, and to remove any such tailrace in order to replace it with a tailrace of the same or a different size and construction (Appendix B, p. 8).

5.3.5.10 Bridge Street Power Station

In the 1984 *Great Deed,* Boott obtained an easement to operate, maintain, repair and replace the existing penstocks leading to the turbines of Bridge Street Power Station

from the Eastern Canal, and to remove any such penstock in order to replace it with a penstock of the same or a different size and construction (Appendix B, p. 8).

Boott also obtained an easement to operate, maintain, repair, and replace the existing tailraces leading from the turbines to the Concord River, and to remove any such tailrace in order to replace it with a tailrace of the same or a different size and construction (Appendix B, p. 8).

5.3.6 Hamilton Canal

In the 1986 *Order of Taking*, MADCR acquired a permanent and exclusive easement to all canal walls, beds or bottoms, and to all dams and lock chambers located in said canal and not otherwise noted for the following purposes (Appendix C, p. 33):

a) Support of all fixtures or structures of the Commonwealth now or hereafter attached;
b) Preservation and conservation;
c) Supplemental maintenance in addition to that performed by the Condemnees (the prior or current owner) and their successors and assigns;
d) Landscaping and erection of exhibits and structures;
e) Placement of barriers and fences;
f) Placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature;
g) Placement of lighting and other utilities;
h) Operation and maintenance of boat locking chambers, if any, for any and all purposes; and
i) Any and all other uses consistent with the operation of the canal system as a park.

As understood based on a review of the described documents, MADCR has permanent and exclusive rights to all Hamilton Canal walls, beds or bottoms for purposes a-i listed above. The expressed exclusivity of this easement indicates that MADCR's rights to implement any of those purposes at or in the Hamilton Canal precede the rights of all other parties. Additionally, through the 1995 *Grant of Easement*, MADCR conveyed to NPS easement rights at various structures and parcels of the Hamilton Canal.

As described below, structures and fixtures within the Hamilton Canal have mixed easement rights, with certain structures sharing similar rights among different parties. The boundaries of easements to structures are assumed to follow the boundaries of ownership, which are depicted in the Appendix A, Appendix E, and the associated GIS database.

5.3.6.1 Hamilton Gatehouse

The 1984 *Great Deed* conveyed to Boott an easement for the right to enter and maintain real and personal property in the Hamilton Gatehouse. Said easement consists of the

exclusive right of operation and controlling the Hamilton Gatehouse, and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms inside Hamilton Gatehouse. Boott has the right to access Hamilton Gatehouse for repair and installation of the machinery and equipment, gauge equipment, and such other mechanisms located inside the gatehouse (Appendix B, p. 2, 5).

The 1986 *Order of Taking* conveyed to MADCR a permanent easement in the Hamilton Canal walls, beds or bottoms for support of the Hamilton Gatehouse, structures, and fixtures, as well as the right to access the Hamilton Gatehouse (Appendix C, p. 16).

The 1995 *Grant of Easement* granted NPS the right to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore the Hamilton Gatehouse (Appendix D, p. 3).

5.3.6.2 Hamilton Power Station

In the 1984 *Great Deed,* Boott obtained an easement to operate, maintain, repair and replace the existing penstocks leading to the turbines of Hamilton Power Station from the Hamilton Canal, and to remove any such penstock in order to replace it with a penstock of the same or a different size and construction (Appendix B, p. 8).

Boott also obtained an easement to operate, maintain, repair, and replace the existing tailraces leading from the turbines to the Concord River, and to remove any such tailrace in order to replace it with a tailrace of the same or a different size and construction (Appendix B, p. 8).

5.4 Resource Rights in the Lowell Canal System

Boott reviewed many sources to understand the resource rights to the Lowell canal system, including planning documents, the MOU, the 1984 *Great Deed* between Proprietors and Boott (Appendix B), the 1986 *Order of Taking* (Commonwealth of Massachusetts 1986), and the 1995 *Grant of Easement* (Appendix D).

For this study, resource rights are classified as such if they are owned by or issued to a party independently from any physical structure. The ownership and rights of physical resources, such as the canal system and gatehouses, are not discussed in this section because those rights are limited to specific structures and thus are addressed above in Sections 5.2 and 5.3.

5.4.1 Recreational Resource Rights of the Lowell Canal System

The 1977 *Report of the LHCDC* and the 1980 *Details of the Preservation Plan* indicated the Commonwealth agreed to preserve the canal system and develop its recreational potentials. The Commonwealth would also undertake the landscaping, repair and maintenance of all the basic canal structural components, canal related structures and canal related land for recreational use. By letter to dated May 14, 1980, MADCR stated that they were currently in the process of negotiating purchase rights to the Lowell canal system which would allow for recreational boating in the canals, stating further that use of the canals and implementation of the boating program were key elements of the Lowell Heritage State Park (Commonwealth 1980).

Through the 1986 *Order of Taking*, MADCR purchased "the exclusive right to use water in the entire canal system and the Merrimack River for recreational, educational, and navigational purposes" and the purposes shall be non-consumptive with respect to Boott's hydroelectric generation (Appendix C). Included in the 1986 *Order of Taking* is a permanent and exclusive easement to MADCR for all canal walls, beds, or bottoms throughout the canal system for purposes consistent with the use of the canal system as a recreational park. These purposes specifically include placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature (Appendix C). The 1995 *Grant of Easement* from MADCR to LNHP did not convey these exclusive recreation rights to LNHP, but does allow LNHP to hold boat tours through certain segments of the canal system (Appendix D).

The *1990 Preservation Plan Amendment* stated this about recreational resources of the canal system:

> "In general, water taxis, dinner boats, and other organized boating programs will be encouraged, subject to permission from the Heritage State Park [MADCR] which controls recreational boating rights on the canals."

In 1991, MADCR, the NPS, and Boott executed the MOU, which specifically identifies recreational resource rights as residing with MADCR, further stating MADCR was to "act

on all special use permit requests for the recreational use of the Lowell canal system and provide copies of approved permits to Boott Hydro and Proprietors and the NPS."

Conceptual planning documents, legal ownership and easement documents, as well as the MOU, are all consistent regarding recreational resource rights. MADCR owns exclusive rights to use the entire canal system for recreational, educational, and navigational purposes. MADCR holds an exclusive and permanent easement for placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature.

5.4.2 Air Resources of the Lowell Canal System

The 1986 *Order of Taking* transferred to MADCR "all air rights over the canals, including the canal walls and any dams thereon" (Appendix C).

5.4.3 Water and Flowage Resource Rights of the Lowell Canal System

Boott obtained water and flowage rights in the 1984 *Great Deed*. These rights include all riparian rights, water rights and mill rights of the canal system, for the uninterrupted flowage of water through the canals. Other uses of water in the Lowell canal system (e.g., surface water recreation) shall be non-consumptive with respect to hydroelectric generation except for reasonable amounts to operate locking gates. Proprietors retains the right to use up to 100 cfs of water from the canals for fire protection and process water (Appendix B; Appendix C).

5.4.4 Power Production

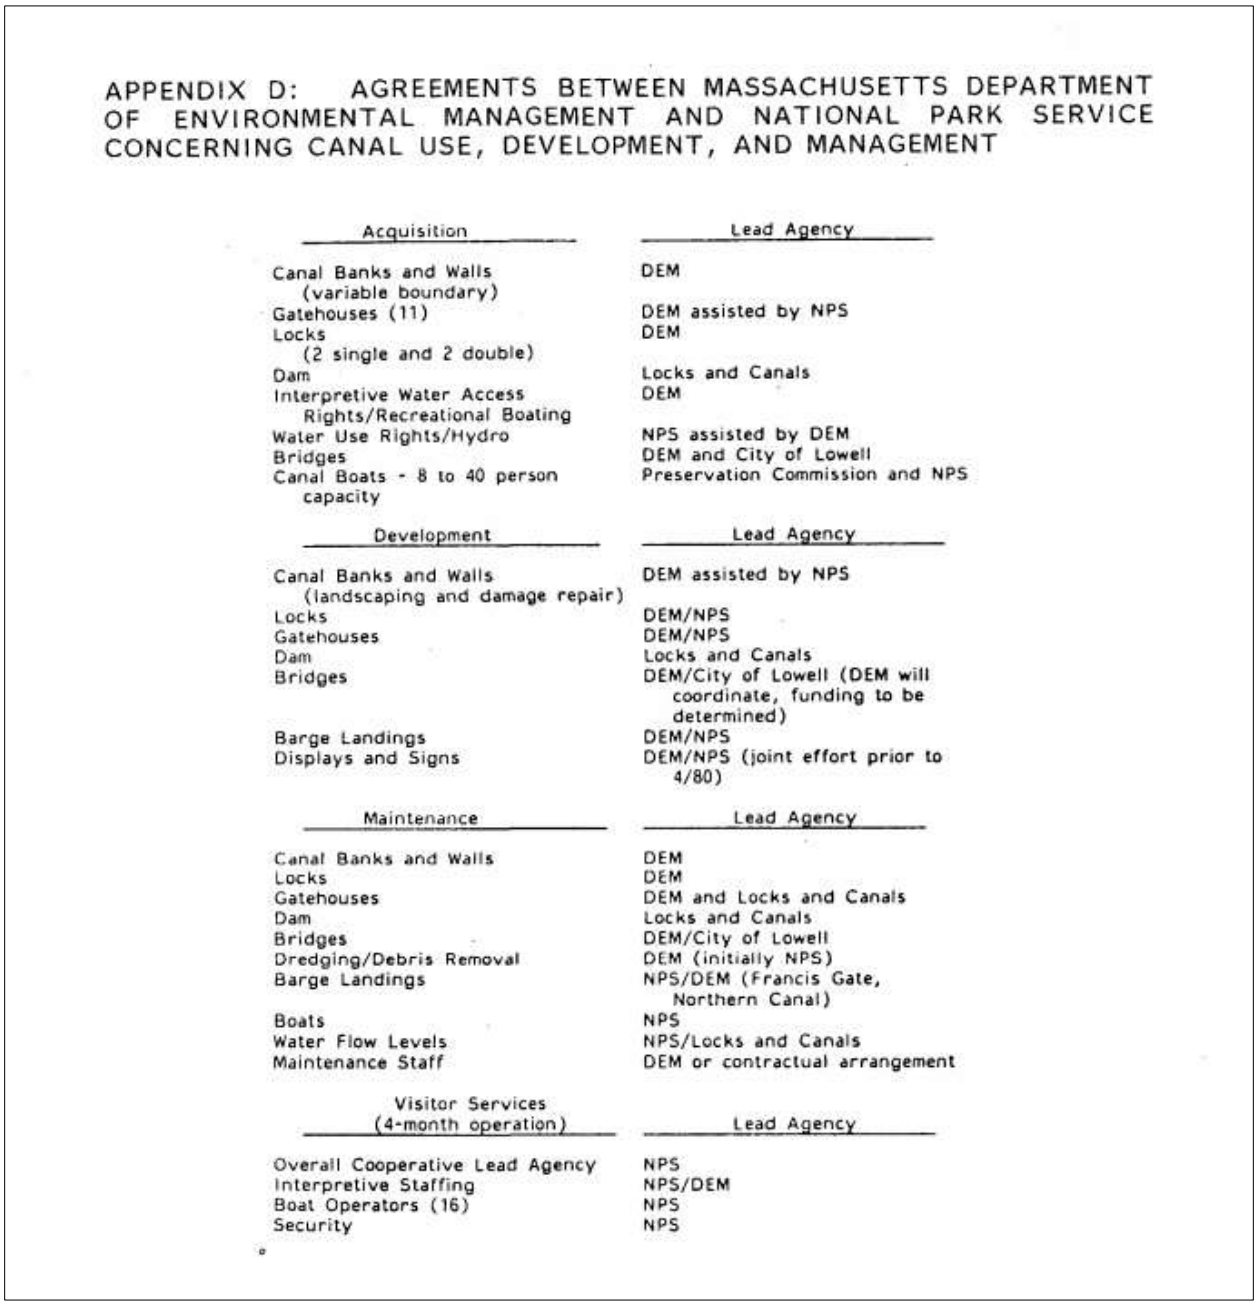
Included in the 1984 *Great Deed* is a conveyance from Proprietors to Boott stating that the land, easements, equipment, and rights are conveyed together with all necessary rights and easements for the purpose of utilizing the facilities, equipment, and fixtures for the purpose of producing and selling power. This includes the right to construct, reconstruct, modify, and rehabilitate such facilities, equipment, and fixtures and to install additional facilities, equipment, and fixtures of like purpose as are necessary, with the right to utilize the premises, structures, facilities, waterways, and equipment to their maximum potential for the purpose of power (Appendix B, p. 9). This is a resource right granted to Boott independently of its rights to specific structures.

5.5 Historical Management Agreements

There are two known historical management agreements between the parties with interests in the Lowell canal system. While these agreements have expired, they present an understanding between the parties of what their individual roles and responsibilities were regarding the Lowell canal system. Given the collaborative approach to ownership and easement rights to the Lowell canal system, the two agreements provide the best insight into delegation of regular management tasks such as ground maintenance, water levels, waterborne trash, and vegetation management.

Following establishment of the LNHP in 1978, MADCR, NPS, and Proprietors entered into an agreement in 1979 regarding management of the Lowell canal system. This agreement establishes MADCR as the lead party responsible for the maintenance of canal structural components, including canal banks and walls. As the lead party, MADCR was responsible for "landscaping and damage repair" to canal banks and walls, with assistance provided by NPS if needed. NPS was charged with the operation of the canal-related exhibits and services, and Locks and Canals (i.e., Proprietors and ultimately Boott) were responsible for the operation and maintenance of Pawtucket Dam and other hydromechanical parts of the Lowell canal system (NPS 1981). This agreement is presented below as Figure 5-2 and fully published in the 1981 FGMP.

Figure 5-2. 1979 Canal System Management Agreement



APPENDIX D: AGREEMENTS BETWEEN MASSACHUSETTS DEPARTMENT OF ENVIRONMENTAL MANAGEMENT AND NATIONAL PARK SERVICE CONCERNING CANAL USE, DEVELOPMENT, AND MANAGEMENT

Acquisition	Lead Agency
Canal Banks and Walls (variable boundary)	DEM
Gatehouses (11)	DEM assisted by NPS
Locks (2 single and 2 double)	DEM
Dam	Locks and Canals
Interpretive Water Access Rights/Recreational Boating	DEM
Water Use Rights/Hydro	NPS assisted by DEM
Bridges	DEM and City of Lowell
Canal Boats - 8 to 40 person capacity	Preservation Commission and NPS

Development	Lead Agency
Canal Banks and Walls (landscaping and damage repair)	DEM assisted by NPS
Locks	DEM/NPS
Gatehouses	DEM/NPS
Dam	Locks and Canals
Bridges	DEM/City of Lowell (DEM will coordinate, funding to be determined)
Barge Landings	DEM/NPS
Displays and Signs	DEM/NPS (joint effort prior to 4/80)

Maintenance	Lead Agency
Canal Banks and Walls	DEM
Locks	DEM
Gatehouses	DEM and Locks and Canals
Dam	Locks and Canals
Bridges	DEM/City of Lowell
Dredging/Debris Removal	DEM (initially NPS)
Barge Landings	NPS/DEM (Francis Gate, Northern Canal)
Boats	NPS
Water Flow Levels	NPS/Locks and Canals
Maintenance Staff	DEM or contractual arrangement

Visitor Services (4-month operation)	Lead Agency
Overall Cooperative Lead Agency	NPS
Interpretive Staffing	NPS/DEM
Boat Operators (16)	NPS
Security	NPS

In 1991, MADCR, the NPS, and Boott executed the MOU for the purpose of maintaining and operating the Lowell canal system.[6] The MOU was generated after the 1984 *Great Deed* and 1986 *Order of Taking*, and so it best represents an agreement between the parties of what their legal roles and responsibilities were. The MOU assigned specific responsibilities to each party and was filed with the Commission on April 25, 1991 (MOU 1991). The MOU included a provision expiring the agreement five years from the date of signing, with the option for renewal.

Article I of the MOU states that the agreement shall not diminish the rights and interests acquired by MADCR in the 1986 *Order of Taking*. The agreement shall not release or further bind Boott and Proprietors from their obligations under the FERC license or other obligations to maintain the Lowell canal system.

Article II of the MOU directs Proprietors to maintain the structural integrity of the walls, bottoms, and dam structures of the Pawtucket Canal to the extent they have the duty to do so as owner. Proprietors was to provide MADCR with any plans to alter the Pawtucket Canal and to obtain MADCR's written prior approval.

Article III of the MOU discusses the responsibilities of Boott, which includes maintaining canal walls, beds, bottoms, and dam structures to the extent they have a duty to do so as the owner. Article III(C) requires Boott to operate the canal system to provide the appropriate flows and water levels. Articles III(H-I) require Boott to obtain written approval from MADCR regarding any changes to the Gatehouses or canal walls which may affect the historic fabric of the system. Other article provisions require notification of drawdowns, access to the E.L. Field Powerhouse, and the payment of utility costs (heating and gas).

Article IV directed NPS to assist MADCR in the removal of litter and other waterborne trash from the Lowell canal system, and states NPS is responsible for maintaining and cleaning ("including removal of trash") all existing trash booms and safety lines/booms on the Lowell canal system. Article IV of the MOU directed NPS to assist MADCR in the removal and control of vegetation along the canal system, ("particularly that growing on and in the canal walls") and to assist MADCR in performing ground maintenance. NPS was tasked with assisting MADCR with the repair and maintenance of all historic gatehouses, such as the repair of architectural features, cleaning and repair of roof gutters, and the maintenance of locking gates and other mechanical devices.

Responsibilities assigned to MADCR under Article V of the MOU include routine maintenance of the gatehouses, serving as the lead agency for all grounds maintenance, keeping all grass, trees, and shrubs neatly trimmed and in a healthy condition, removing dead or diseased plants, fertilizing, pruning, and thinning of plants (as required), and approving ground maintenance or improvement plans as proposed by NPS. Article V directs MADCR to assist NPS in the removal and control of destructive vegetation along

[6] Proprietors of the Locks and Canals on the Merrimack River was included as a party in the MOU but did not execute the agreement.

the canal system, and to cooperate with the NPS on developing a litter removal program for waterborne litter and trash on the canals. (MOU 1991). MADCR was to implement an annual safety inspection of the locking gates and gate chambers. This article also specified MADCR to reimburse NPS for time and materials for work done on the canal system. Notably, MADCR was to "act on all special use permit requests for the recreational use of the Lowell canal system and provide copies of approved permits to Boott Hydro and Proprietors and the NPS."

Article VI of the MOU directed NPS and MADCR to hold a joint annual meeting to develop an annual building maintenance program, annual destructive vegetation clearing program and canal surface water cleanup program. The annual programs were to be developed in accordance with each agency's budget and seasonal staffing level. Under Article VI, MADCR was also directed to consult with NPS to develop a long-term capital improvement program for the canal system. The minutes of this annual meeting between MADCR and NPS were to be provided to Boott and the Proprietors each year (MOU 1991).

5.6 FERC Jurisdiction

One of the goals for this study was to clarify FERC jurisdiction. Section 23(b)(1) of the Federal Power Act (FPA) requires that each non-federal hydroelectric project, except those with pre-1920 federal permits that are still valid, falls under FERC jurisdiction if it: (1) is located on navigable waters of the United States; (2) occupies lands of the United States; (3) uses surplus water or water power from a government dam; or (4) is located on a body of water over which Congress has Commerce Clause jurisdiction, was constructed or modified after August 25, 1935, and affects interstate or foreign commerce.

All hydropower projects deemed jurisdictional must be licensed by FERC (or exempted from licensure), and the Project Boundary defines the geographical limits of FERC's jurisdiction. The Commission determines the limits of the Project Boundary based on lands and waters needed by the Licensee: (1) to construct and operate its Project and (2) to carry out other non-power project purposes such as fish passage and minimum flow requirements.

The Licensee is required to manage operations within the Project Boundary in accordance with the conditions set forth in the FERC license. Additionally, Section 10(c) of the FPA requires Licensees with to maintain the project works within the Project Boundary in a condition of repair adequate for the purposes of navigation and for the efficient operation of said works in the development and transmission of power, . . . to maintain and operate said works as not to impair navigation, and . . . conform to such rules and regulations as the Commission may from time to time prescribe for the protection of life, health, and property.

The FERC Project Boundary around the project impoundment, continuous project features, and noncontiguous Project works are presented in Exhibit G maps according to the methods required under 18 CFR §4.41(h)(2). The Exhibit G maps for the Lowell Hydroelectric Project were filed with the FLA on April 30, 2021.

As stated in the FLA, Boott proposes to remove the four mill power stations and associated canal infrastructure from the new FERC license. The Project Boundary will be modified to remove much of the downtown canal infrastructure. However, Boott will continue to manage the canal structures, water levels and flows using best practices and consistent with current agreements with the NPS and other stakeholders.

6 Discussion and Conclusion

6.1 Ownership and Easement Rights to the Lowell Canal System

Ownership, easement rights, and use of the canal system in Lowell are complex, with intersecting roles between public agencies and private entities at the local, State, and Federal level. In their request for this study, NPS noted that the eventual goal of this study would be to denote which entity is ultimately responsible for specific resources. Boott's review of the documentation indicated that it is not possible to specify ultimate responsibility for most physical resources of the Lowell canal system because the LNHP was planned, designed, and launched as a collaboration between parties, and legal documents were executed to solidify this approach. From the start of the park's conception in the 1977 *Report of the LHCDC*, the vision has always been "a creative partnership which would go beyond the reach of any single agency or level of government" (LHCDC 1977). Generally, the legal documentation issued in the form of the 1984 *Great Deed*, 1986 *Order of Taking*, and the 1995 *Grant of Easement* does not designate any party to be solely responsible for specific structures.

Ownership of the Lowell canal system is largely determined by the 1984 *Great Deed* and 1986 *Order of Taking*. Components of the canal system are owned by Proprietors, Boott, and MADCR. Proprietors owns much of the Pawtucket Canal and structures of the Pawtucket Canal. Boott owns the Northern Canal, Western Canal, Merrimack Canal, Eastern Canal, and Hamilton Canal. Boott owns specific dams, lock structures, and hydroelectric equipment within the canals they own, and this is largely determined based on elevation. MADCR owns most of the gatehouses and several other historical structures throughout the Lowell canal system.

Easement rights to structures of the Lowell canal system are held by Proprietors, Boott, MADCR, and NPS. In the 1984 *Great Deed*, Boott obtained easement rights, in common with Proprietors, to the Pawtucket Canal and structures of the Pawtucket Canal. These easement rights allow Boott to access, operate, maintain, repair, and replace the Pawtucket Canal and structures of the Pawtucket Canal. In the 1986 *Order of Taking*, MADCR obtained a permanent and exclusive easement to structures of the canal system, including canal walls, beds, and bottoms, for purposes including conservation, preservation, maintenance, and other uses consistent with the use of the system as a park. NPS obtained similar easement rights through the 1995 *Grant of Easement* from MADCR, including the right to maintain, repair, conduct grounds maintenance, and operate boat tours.

Most structures throughout the canal system have overlapping ownership and easement rights. A property owner (Proprietors, Boott, and/or MADCR) has a duty to achieve a reasonable standard of care[7] for the properties under their ownership. Each property

[7] The Standard of Reasonable Care is typically defined as the degree of caution and concern for the safety of self and others that a reasonable person would exhibit.

owner has a right to conduct routine maintenance of their facilities to achieve a standard of reasonable care, but they do not have an obligation to enhance or upgrade their properties. Similarly, a maintenance easement issued in common with others allows the holder to conduct routine maintenance of the property under easement, and allows others holding to also conduct routine maintenance, but the easement holder(s) is not required or permitted to upgrade or enhance the property.

An exclusive easement allows the easement owner to control and implement specific purposes as if they are the owner. MADCR has a permanent and exclusive easement over most of the canal system for the following purposes, which include enhancements and upgrades:

a) Support of all fixtures or structures of the Commonwealth now or hereafter attached;
b) Preservation and conservation;
c) Supplemental maintenance in addition to that performed by the Condemnees (the prior or current owner) and their successors and assigns;
d) Landscaping and erection of exhibits and structures;
e) Placement of barriers and fences;
f) Placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature;
g) Placement of lighting and other utilities;
h) Operation and maintenance of boat locking chambers, if any, for any and all purposes; and
i) Any and all other uses consistent with the operation of the canal system as a park.

Given that MADCR's exclusive easement is throughout most of the canal system, it overlaps significantly with Boott and Proprietors' owned property. It is understood that Boott, Proprietors, and MADCR have a duty and right to maintain properties under their ownership to achieve a standard of reasonable care. Owners do not have an obligation or duty to upgrade or enhance their property. However, MADCR's exclusive easement throughout most of the Lowell canal system gives them the right to implement any of the purposes noted above, which include enhancements and upgrades, as if they were the owner. Accordingly, in cases of overlapping ownership and easement rights, it will almost entirely depend on the nature of the effort to determine obligations and responsibilities.

6.2 Resource Rights to the Lowell Canal System

For this study, resource rights were classified as such if they are owned by or issued to a party independently from any physical structure. Four resource rights were identified based on a review of the 1984 *Great Deed*, the 1986 *Order of Taking*, and the 1995 *Grant of Easement*.

Recreational resource rights are exclusively owned by MADCR. In early conceptual planning documents, MADCR was presented as the party that would own, implement, and manage any recreational resources. MADCR obtained such rights in the 1986 *Order of Taking*, including the exclusive right to use water for recreational, educational, or navigational purposes, and permanent and exclusive rights to build wharves, docks, and boat ramps. The 1990 *Preservation Plan Amendment* and the 1991 MOU, both issued after MADCR received all recreation rights, discuss MADCR's role as encouraging, managing, and approving different recreational activities throughout the Lowell canal system.

Air resource rights have been owned by MADCR since issuance of the 1986 *Great Deed*. Water and flowage rights are owned by Boott and Proprietors, as established in the 1984 *Great Deed*.

Additionally, as stated in the *1984 Great Deed*, Boott was granted the right to utilize structures of the canal system to their maximum potential for the purpose of power, a resource right granted to Boott independently of its rights to specific structures.

6.3 Historical Management Agreements

There are two known historical management agreements between the parties with interests in the Lowell canal system. The two agreements provide the best insight into delegation of regular management tasks such as grounds maintenance, water levels, waterborne trash, and vegetation management.

The 1979 agreement states that NPS and MADCR were responsible for development and maintenance of canal walls and banks, including landscaping and repair and dredging/debris removal, as well as developing locks, gatehouses, bridges, barge landings, and displays and signs. Proprietors (ultimately Boott) were responsible for development and maintenance of the Pawtucket Dam, water levels and flows, and gatehouses.

The 1991 MOU was executed between MADCR, the NPS, and Boott. As owners of the canal walls, the MOU directed Proprietors and Boott to maintain the structural integrity of the walls, bottoms, and dam structures to the extent they have the duty to do so as owner (maintain a standard of reasonable care). Proprietors and Boott were to provide MADCR with any plans that might alter the historic fabric of the canal system, and to obtain MADCR's written prior approval. Boott was directed to operate the canal system to provide the appropriate flows and water levels.

The MOU directed NPS and MADCR to collaborate on most daily, routine management tasks regarding the Lowell canal system. They were to remove litter and other waterborne trash from the Lowell canal system, and maintain and clean all existing trash booms and safety lines/booms on the Lowell canal system. NPS and MADCR were directed to hold a joint annual meeting to develop an annual building maintenance program, annual destructive vegetation clearing program ("particularly that growing on and in the canal walls") and canal surface water cleanup program. NPS was tasked with assisting MADCR with the repair and maintenance of all historic gatehouses, such as the repair of architectural features, cleaning and repair of roof gutters, and the maintenance of locking gates and other mechanical devices.

7 Variances from FERC-Approved Study Plan

The Resources, Ownership, Boundaries, and Land Rights Study was conducted in full accordance with the methods described in the FERC-approved study plan.

Appendix B - 1984 *Great Deed*

See Agmt B. 7444 P 302

DEED, BILL OF SALE AND GRANT OF EASEMENTS

PROPRIETORS OF THE LOCKS AND CANALS ON MERRIMACK RIVER and BOOTT MILLS, both Massachusetts corporations with offices at Foot of John Street, Lowell, Middlesex County, Massachusetts (together with their successors and assigns, the "Grantors"), for TEN DOLLARS and other good and valuable consideration, hereby grant with warranty covenants to BOOTT HYDROPOWER, INC., a Massachusetts corporation with offices at Foot of John Street, Lowell, Middlesex County, Massachusetts (together with its successors and assigns, the "Grantee"), the following land, easements, property and interests and rights in property all located (except as expressly noted) in Lowell, Middlesex County, Massachusetts:

A. Land, Waterways, Improvements. The land, together with the buildings, improvements, fixtures and other property appurtenant thereto, consisting of those lands, canals, dams or portions thereof and other property set forth below (collectively, the "Parcels"):

1. Parcel I: That certain parcel of land, situated on the northerly side of Jackson Street, being shown as a right of way on a plan of land entitled "Compiled Plan in Lowell, Mass. owned by Courier-Citizen Company" dated March 10, 1978, recorded with Middlesex County North District Registry of Deeds (the "Registry"), Book of Plans 126, Plan 112.

2. Parcel II: That portion of the Merrimack River bounded as follows:

STARTING	from a point at the intersection of the easterly end of the upstream side of the Pawtucket Dam and the shoreline of the Merrimack River, thence
NORTHEASTERLY	along the shoreline of the Merrimack River to the intersection of the shoreline with land of The Commonwealth of Massachusetts, University of Lowell, described as Parcel 2 on a certain "Plan of Land in Lowell, Massachusetts prepared for Proprietors of Locks & Canals on Merrimack River and Massachusetts Wholesale Electric Co.; June 14, 1983" and recorded with the Registry in Plan Book 141, Plan 139, thence
NORTHWESTERLY	along said Parcel 2 to the centerline of the Merrimack River and continuing in the same direction to the opposing shoreline of the Merrimack River, thence
SOUTHWESTERLY	along the shoreline of the Merrimack River to the point of intersection with the westerly

end of the upstream side of the Pawtucket Dam, and thence

EASTERLY along the upstream side of the Pawtucket Dam to the point of beginning.

The Grantors also convey all their right, title and interest, if any, in and to the premises subject to the Lease dated September 28, 1983 between the University of Lowell and Boott Mills, notice of which Lease is recorded with the Registry in Book 2680, Page 281, said premises being shown as Parcels 1 and 2 on a certain Plan entitled "Plan of Land in Lowell, Massachusetts prepared for Proprietors of Locks and Canals on Merrimack River and Massachusetts Wholesale Electric Co.; June 14, 1983" and recorded with the Registry in Plan Book 141, Plan 139; provided, however, that the rights described in this paragraph shall not include any rights which Boott Mills has as lessee under said Lease.

Said Parcel II includes the Pawtucket Dam in its entirety and any and all equipment and mechanisms located in or on said dam or appurtenant thereto, including without limitation fishways and flashboards. Said Parcel II is subject to the rights of The Commonwealth of Massachusetts, the City of Lowell and others legally entitled to the use, maintenance and operation of the University Avenue Bridge and, pursuant to Chapter 132 of the Massachusetts Acts of 1835, the School Street Bridge crossing the same.

3. Parcel III: The land and waterways historically known and designated as follows:

A. The Northern Canal
B. The Western Canal
C. The Lower Western Canal
D. The Eastern Canal
E. The Merrimack Canal
F. The Lawrence Canal
G. The Hamilton Canal
H. The Moody Street Feeder

Said canals are conveyed in their entirety to the exterior plane of the existing canal walls, and including canal fences located thereon, the fee underlying the same, and all waterways and sluiceways forming a part of such canals, and including all dams and gates contained therein and including, but not limited to, the following dams and gates:

A. The Lawrence Dam
B. The Hall Street Dam
C. The Rolling Dam
D. The Merrimack Gates
E. The Boott Dam
F. The Northern Canal Headgates

Said dams and gates are conveyed together with the fee to the land underlying the same and all equipment and

mechanisms located in or on said dams and gates or appurtenant thereto, including, but not limited to, wasteways, penstocks, tailraces, headgates and racks.

Parcel III includes all Grantor's interest in the following bridges crossing the canals described above:

A.	Over Eastern Canal:	1. East Merrimack Street 2. Bridge Street
B.	Over Merrimack Canal:	1. Merrimack Street (only 25 feet either side of center line)
C.	Over Western Canal:	1. Merrimack Street (only 25 feet either side of center line)
D.	Over Northern Canal:	1. Suffolk Street 2. Pawtucket Street

Parcel III is subject to rights of The Commonwealth of Massachusetts, the City of Lowell and others legally entitled to the use, maintenance and operation of the above described bridges and other existing bridges crossing the canals described above.

Grantors hereby expressly reserve from the within grant, and Parcel III does not include, that portion of those structures, historically known and designated as set forth below, in or above the aforementioned canals, dams and gates which is above the following noted elevations above Mean Sea Level, National Geodetic Vertical Datum (hereinafter collectively referred to as the "Gatehouses"):

A. Northern Canal Gatehouse, above 101.2 feet M.S.L., including the Northern Canal Gatehouse Locks, above 82.7 feet M.S.L.
B. Tremont Gatehouse, above 90.2 feet M.S.L.
C. Hamilton Gatehouse, above 90.2 feet M.S.L.
D. Massachusetts Wasteway Gatehouse, above 80.2 feet M.S.L.
E. Rolling Dam Gatehouse, above 83.7 feet M.S.L.
F. Moody Street Feeder Gatehouse (also known as Merrimack Gatehouse), above 92.2 feet M.S.L.;
G. Boott Dam Gatehouse, above 74.2 feet M.S.L.;

however, Parcel III does include all mechanisms, controls and other machinery and equipment located above said

elevations which are necessary for the control and operation of the lands, dams and gates upon which the Gatehouses rest.

The Gatehouses are hereby intended to be severed from the lands, dams and gates upon which they rest, so that the Gatehouses will be considered real property of the Grantors separate from said land, dams and gates, and each may forever hereafter independently be conveyed, transferred, mortgaged and leased.

Grantors also hereby expressly reserve from the within grant, and Parcel III does not include, the so-called "Great River Wall," being the land and structures located thereon (including without limitation the Northern Canal Wastegate House, also called the High Bridge Gatehouse) dividing the Northern Canal and the Merrimack River which starts at the Northern Canal Gatehouse and extends northeasterly to the intersection of the Northern Canal with land of The Commonwealth of Massachusetts, University of Lowell, described as Parcel 1 on a certain "Plan of Land in Lowell, Massachusetts prepared for Proprietors of Locks & Canals on Merrimack River and Massachusetts Wholesale Electric Co.; June 14, 1983" and recorded with the Registry in Plan Book 141, Plan 139.

Said Parcel III also does not include those portions of canal walls previously conveyed as evidenced by instruments recorded with the Registry in Book 1428, Page 185, Book 1608, Page 357 and Book 1690, Page 429.

B. Easements. The following easements, newly created hereby, held or hereafter acquired by the Grantors, which are hereby made appurtenant to the Parcels:

1. Access and Repair. The Grantors grant an easement over the remaining lands of the Grantors, and grant the benefit of easements over lands of others, in each case which the Grantors may now or hereafter own, possess or have the right to use, for the purpose of obtaining access to the Parcels from public ways, for the providing of utilities necessary for the operation of the Parcels and entering on such portions of the property adjacent to the Parcels with personnel, equipment and materials for the purposes of maintaining, repairing, replacing, reconstructing and rebuilding the Parcels or any property located thereon.

2. Easement to Pawtucket Canal. The Grantors further grant an easement, in common with the Grantors and others entitled thereto, to the Pawtucket Canal, Lower Pawtucket

Canal, the Pawtucket Canal Guard Gate and Locks, the Swamp Locks Dam and the Lower Locks Dam for the uninterrupted flowage of water to the canals described in Parcel III above, together with the right to install conduits, pipes and wiring therein and the right to maintain, repair and replace the canal walls and fences on and bridges over said Pawtucket and Lower Pawtucket Canals and to maintain and operate the Pawtucket Canal Guard Gate and Locks, the Swamp Locks Dam and the Lower Locks Dam.

3. Easement for Access to Structures. The Grantors further grant easements to enter, and maintain real and personal property in, the Gatehouses and in addition those other structures in or adjacent to the above said canals and dams historically known and designated as follows:

A. Blacksmith Shop
B. Old Guard Locks Gatehouse
C. Swamp Locks Gatehouse
D. Lower Locks Gatehouse
E. Great River Wall (as described in Parcel III above), including without limitation the Northern Canal Wastegate House (also called the Highbridge Gatehouse)

Said easements consist of the exclusive right of operating and controlling the Gatehouses and the above said structures and locating, keeping in place, maintaining, replacing, operating, controlling and disposing of the control machinery and equipment, gauge equipment and other mechanisms located therein and, in common with the Grantors and others entitled thereto, for access to and for maintenance and repair of the Gatehouses and the above said structures and access to and maintenance, repair and installation of the control machinery and equipment, gauge equipment and such other mechanisms located therein as the same may from time to time be repaired, reconstructed or replaced. The Grantors further grant an easement over other lands of the Grantors, and grant the benefits of easements owned by Grantors over lands of others, in each case which the Grantors may now or hereafter own, possess or have the right to use, for powerlines, utilities and for access to and egress from the above said premises and public ways.

C. Water and Flowage Rights. The Grantors hereby grant to the Grantee any and all riparian rights, water rights and "Mill Powers" which the Grantors may have in the water flowing in the Merrimack River in Middlesex County,

Massachusetts, and Hillsborough County, New Hampshire. Such rights include any and all water rights which may exist regardless of how acquired, including, without limitation, any and all water rights which Grantors may have by virtue of riparian rights or any and all water rights which may have been specifically granted to Grantors, or acquired through the conveyance of interests in any dam or flowage rights or acquired by prescription, whether now owned or hereafter acquired. Without limiting the generality of the foregoing, said rights include:

(i) the right, without payment of compensation therefor, to utilize all the waters of the Merrimack River upstream of the Pawtucket Dam, and the right to extract and use such water, subject only to the rights of riparian owners along the Merrimack River and rights previously granted in (x) Agreement between Grantors and the City of Lowell et al. dated June 21, 1875 recorded with the Registry in Book 128, Page 113, (y) Agreement between Grantors and the City of Lowell et al. dated December 31, 1875 recorded with the Registry in Book 114, Page 121, and (z) Release among Grantors and The Commonwealth of Massachusetts dated April 17, 1896 recorded with the Registry in Book 274, Page 225.

(ii) the right, without payment of compensation therefor, to dam and divert all the water from the Merrimack River for the distance from the Pawtucket Dam to the intersection of the Merrimack River and the Concord River, through the Pawtucket or Northern Canals or othewise, and the right to extract and use such water, and

(iii) the right, without payment of compensation therefor, to overflow, flood, and cover to a height of 92.2 feet above Mean Sea Level (National Geodetic Vertical Datum) from July through February, and to a height of 91.2 feet above Mean Sea Level from March through June, real property in Middlesex County, Massachusetts, and Hillsborough County, New Hampshire, adjacent to the Merrimack River upstream from the current site of the Pawtucket Dam with flood water, slack space water or back water created by the operation of a dam or dams across the Merrimack River in the vicinity of the current site of the Pawtucket Dam together with the right to enter on such real property from time to time to maintain the dam or dams and the reservoir created by such dam or dams and to

clear the reservoir of any structures, growth or other obstruction below elevation 92.2 feet above Mean Sea Level which interfere with the operation of such dam or dams across the Merrimack River.

Said rights are subject to rights previously conveyed pursuant to the Agreement dated March 7, 1983 between the Grantors and James T. Lichoulas, as trustee for the Appleton Trust, as amended, recorded with the Registry in Book 2611, Page 630 and pursuant to the Agreement dated February 1, 1982 among the Grantors, Corporation Investments, Inc., Kenneth M. Scagel, Sr., Kenneth M. Scagel, Jr., Atlantic Associates and Massachusetts Hydro Associates recorded with the Registry in Book 2611, Page 624.

D. Reservations. The Grantors for themselves, their successors and assigns, reserve the right to use the surface water in the canals described in Parcel III above and the Pawtucket Canal for recreation and transportation purposes, provided that said use and operation in any and all events does not interfere with the use and operation of the Parcels for the generation of power. The Grantors also reserve for themselves, their successors and assigns, the right to use up to a combined total of 100 cubic feet per second of water in such canals, and the right to use such canals, to maintain and operate existing steam distribution and fire protection systems owned by the Grantors and to provide process water for customers of the Grantors, including improvements to or expansions of such systems within said limitations of flowage.

Subject to the easements herein granted and conveyed, the Grantors further reserve for themselves, their successors and assigns, any and all surface land and all air space above the premises described above as Parcel III, and further reserve the right to have access to and occupy, use and develop such surface land and air space; provided, however, that the occupation, use and development of such surface land and air space in any and all events shall neither interfere in any way with the use or operation of any of the Parcels, the facilities or rights described herein nor any other property of Grantees used for the purpose of generating hydroelectric power nor interfere in any way with access to the premises described above as Parcel III for purposes of maintaining, repairing, replacing, reconstructing and rebuilding the premises described as Parcel III as may from time to time become necessary in connection with the operation and upkeep of the same.

E. Fixtures and Equipment. The Grantor hereby grants to Grantees all hydro and generating equipment of the Grantors, including all turbines, generators, governors, exciters, control panels, main breakers and extra parts, tools, patterns, blueprints and performance data, transformers, substations, electrical transmission lines, and related mechanisms necessary for the production and transmission of electricity to the generator control panels. Without limiting the generality of the foregoing, said property includes the turbines and generators (the "Turbines") listed and described in Exhibit A and all appurtenant equipment and fixtures located in the rooms housing the same and the electrical transformers (the "Transformers") listed and described in Exhibit B.

F. Easements. The property described in Section E above is conveyed with the benefit of the following easements:

1. Turbine Rooms. An easement to enter, occupy, use, maintain and repair the rooms in which the Turbines are located for the purpose of keeping in place, maintaining, operating, repairing, replacing and otherwise dealing with the Turbines and all appurtenant equipment and fixtures located in the rooms housing the same. Included is the right at all times to enter and have unrestricted access to such rooms for such purposes, and to remove or alter the walls thereof (both interior and exterior) to the extent necessary or convenient to such purposes, provided that such walls shall be restored to their original condition (or to a condition having a similar functional utility and appearance) promptly upon completion of the activity leading to their removal or alteration.

2. Penstocks and Tailraces. An easement to operate, maintain, repair and replace the existing penstocks leading to the Turbines from the Merrimack Canal, Eastern Canal or Hamilton Canal, as the case may be, and to remove any such penstock in order to replace it with a penstock of the same or a different size and construction. Also an easement to operate, maintain, repair and replace the existing tailraces leading from the Turbines to the Pawtucket Canal, the Concord River or the Merrimack River, as the case may be, and to remove any such tailrace in order to replace it with a tailrace of the same or a difference size and construction.

3. Transformers. An easement to keep in place, locate, operate, maintain, repair, remove and replace the Transformers and an easement for unrestricted access thereto for such purposes.

4. Transmission Lines. Also the right to use, maintain and repair existing electrical transmission lines from the generator control panels, including all substations and transformers, of the Grantors for the purpose of operating the aforesaid equipment and facilities, until such time as the aforesaid equipment and facilities are permanently disconnected from such transmission lines. Also the right to construct, reconstruct, operate, keep in place, maintain, repair, remove and replace electrical transmission lines and lines for the transmission of intelligence by electricity, including connection to the generator control panels, substations, transformers, junction boxes, wires, cables, conduits and other necessary appurtenances thereto, upon, over, across and under the lands, buildings, structures and easements of the Grantors for the purpose of generating and selling power, whether generated by the facilities described herein, or by other power facilities owned by the Grantee in the City of Lowell.

G. General. The land, easements, equipment and rights described herein are conveyed together with all necessary rights and easements for the purpose of utilizing the aforesaid facilities, equipment and fixtures for the purpose of producing and selling power, including the right to construct, reconstruct, modify and rehabilitate such facilities, equipment and fixtures now existing and to install additional facilities, equipment and fixtures of like purpose, including without limitation an unrestricted right of access over other lands, easements and buildings of the Grantors from existing public ways as are necessary to fulfill the purposes of the within grant and conveyance and the right to utilize the within conveyed premises, structures, facilities, waterways and equipment to their maximum potential for such purposes.

For Grantors's title, see the following:

Deed of James Parkhurst dated September 20, 1792, recorded with Middlesex South District Registry of Deeds, Book 108, Page 461;

Deed of Benjamin Melvin dated November 10, 1795, recorded with Middlesex South District Registry of Deeds, Book 115, Page 518;

Deed of Joseph Tyler dated March 17, 1797, recorded with Middlesex South District Registry of Deeds, Book 125, Page 97;

Deed of Nathan Tyler dated February 17, 1798, recorded with Middlesex South District Registry of Deeds, Book 128, Page 223; and

Deed of Merrimack Manufacturing Co. dated January 2, 1826, recorded with Middlesex South District Registry of Deeds, Book 269, Page 1.

The extent and nature of the consideration herein is such that deed stamps are not required.

Reference is made to plans available for inspection at the offices of Chicago Title Insurance Co., which is currently located at 133 Federal Street, Boston, Massachusetts, for general identification and location of certain of the premises conveyed hereby.

IN WITNESS WHEREOF, Proprietors of the Locks and Canals on Merrimack River and Boott Mills have caused their corporate seals to be hereto affixed, and these presents signed in their name and behalf by Melvin G. Lezberg, their President, hereunto duly authorized, this 16th day of January, 1984.

AFFIDAVIT

I, Richard G. Drury, on oath depose and say that while the premises described in the within instrument are not the same as described in or conveyed by prior recorded instruments identified sufficiently to locate the place of recording within the Registry, the within instrument does not create any new boundaries within the meaning of Mass. General Laws, Chapter 183, § 6A, since the premises being conveyed are bounded by known monuments consisting of canal walls, dams and river banks which have been established for over one hundred years.

Dated this 16th day of January 1984.

Richard G. Drury

COMMONWEALTH OF MASSACHUSETTS

Middlesex, ss. January 16, 1984

Appendix C -
1986 *Order of Taking*

BK3830 PG 70

77480

ORDER OF TAKING

The Commonwealth of Massachusetts (the "Commonwealth"), acting by and through its Commissioner of Environmental Management, of 100 Cambridge Street, Boston, Massachusetts 02202, by virtue of the authority conferred by Chapter 132A, Sections 3 and 3A of the General Laws, does hereby take in the varying interests described in the attached Schedule "I" for conservation and recreation purposes, in accordance with Chapter 132A, Sections 3 and 3A of the General Laws, the parcels of land located in Lowell, Middlesex County, Massachusetts, containing the areas and being described as set forth in the attached Schedule "II" and being commonly referred to as the land and water of Proprietors of the Locks and Canals on Merrimack River and other supposed owners hereinafter described ("Condemnees").

All of the aforesaid premises are shown and delineated on a plan entitled "Plan of Land of Lowell Canal System for the Department of Environmental Management of land located in Lowell, Massachusetts," surveyed by Atlantic Engineering and Survey Consultants of Lynn, Massachusetts variously dated from May 23, 1983 to August 13, 1983, Scale 1" = 40', and recorded herewith.

Together with the right, title and interest of Condemnees in and to those rights of way, access, wharves, docks,

See Plan Book 151 Plan 69

Rec B 3830 P 70

Rec B 3888 P 69

Rec B3888 P 103

83 DEC 15 11 2:36

shore and water rights, insofar as the same may be appurtenant to the canals and land hereby acquired, as stated on Schedule "I".

Said premises are acquired subject to the rights, privileges and easements as set forth in a deed of Boott Mills, et al to Boott Hydro dated January 16, 1984 and recorded with the Middlesex North Registry of Deeds at Book 2690, Page 542, except as expressly set forth herein.

Trees and structures, if any, upon the land are included in the taking.

Excepted from the rights herein taken by the Commonwealth are all easements for wires, pipes, conduits, poles and other appurtenances for the conveyance of water, sewage, gas, oil, electricity and telephone communication now lawfully in or upon the premises hereby taken.

For damages sustained by reasons of the aforesaid taking, and in accordance with the provisions of Chapter 79, Section 6 of the General Laws, as amended, awards have been made. The right is reserved to amend the award or to increase the amount of damages to be paid at any time prior to payment thereof for good cause shown.

SUPPOSED OWNERS

1. Proprietors of the Locks and Canals on Merrimack River.

2. Boott Hydropower, Inc.

3. Boott Mills

all with offices at Foot of John Street, Lowell, Middlesex County, Massachusetts, and

4. General Electric Credit Corporation

(all referred to herein as Condemnees), each as to their respective interests in any of the water, land or canals described in Schedule II.

All names of owners herein given, although supposed to be correct, are such only as to matters of opinion and belief.

IN WITNESS WHEREOF, the Commonwealth of Massachusetts has caused these presents to be executed in its name and behalf by James Gutensohn, its Commissioner of Environmental Management, hereunto duly authorized who does hereto set his hand this 1st of December, 1986.

IN ADDITION TO THE ABOVE PARCELS, the Commonwealth hereby acquires:

A. A permanent and exclusive easement in all canal walls and beds or bottoms and in all dams and boat lock chambers located in said canals and not otherwise referred to in this Schedule I, for the following purposes:

(a) support of all fixtures or structures of the Commonwealth now or hereafter attached;

(b) preservation and conservation;

(c) supplemental maintenance in addition to that performed by the Condemnees and their successors and assigns;

(d) landscaping and erection of exhibits and structures;

(e) placement of barriers and fences;

(f) placement and attachment of docks, wharves, walls and boat ramps of a temporary or permanent nature;

(g) placement of lighting and other utilities;

(h) operation and maintenance of boat locking chambers, if any, for any and all purposes; and

(i) any and all other uses consistent with the operation of the canal system as a park.

B. All air rights over the canals, including the canal walls and any dams thereon, to the extent not already lawfully obstructed or occupied, for so long as such lawful obstruction or occupation continues uninterrupted in its present form.

C. The exclusive right to use the water in the entire canal system and the Merrimack River for recreational, educational and navigational purposes, which use shall be nonconsumptive with respect to hydroelectric power generation except for reasonable amounts to operate locking gates.

ALL OF THE TITLE, RIGHTS AND INTEREST DESCRIBED IN SCHEDULES I AND II ARE TAKEN BY THE COMMONWEALTH SUBJECT TO THE FOLLOWING LIMITATIONS AND RESERVATIONS:

A. Such title, rights and interest will be used solely for public park purposes and shall not be used by the Commonwealth or its successors or assigns for any commercial or nonpublic purpose.

B. Condemnees and their successors and assigns retain the right of access to all parcels, buildings and structures to the extent necessary for the maintenance and operation of hydroelectric power production facilities.

C. There shall be reserved in the Condemnees, their successors and assigns an easement for wires, pipes, conduits, valves, pumps, poles and other equipment presently existing or hereafter to be installed for the operation, maintenance and extension of steam, fire protection, water supply systems, electricity, sewage, gas, oil, and telephone communication, provided that all such wires, pipes, conduits, valves, pumps, poles and other equipment to be installed in the future shall not be inconsistent with the Commonwealth's use and operation of the canal system as a public park, and provided further that all such wires, pipes, conduits, valves and pumps to be installed in the future relating to electricity, sewage, gas, oil, and telephone communication shall be installed below the surface of the land or water.

PROPOSED DESCRIPTION OF LAND

PARCEL: 13B

Beginning at an iron pin set at the northwesterly corner of Broadway and Madonna Circle; thence along the northerly line of Broadway

S 82° -56' -05" W, a distance of about seventy feet (70) to a point at the back edge of the easterly granite wall of the Pawtucket Canal; thence along the back edge of said canal wall

NORTHERLY, more or less, a distance of about one hundred sixty-three feet (163) to an angle in said wall; thence along the back edge of a granite wall appurtenant to the Pawtucket Canal as follows:

SOUTHEASTERLY, more or less, a distance of about twenty-six feet (26),

NORTHEASTERLY, more or less, a distance of about three feet (3), and

NORTHWESTERLY, and WESTERLY, more or less, a distance of about ninety-four feet (94) to a point on said wall at Parcel 8-C; thence along the easterly line of Parcel 8-C

NORTHERLY, more or less, a distance of about thirteen feet (13) to the southerly face of the Hydraulic Gatehouse; thence by the face of said gatehouse

N 69° -11' -23" E, a distance of about sixty-seven feet (67) to the southeasterly corner thereof, and

N 20° -48' -37" W, a distance of nineteen and 39/100 feet (19.39) to the northeast corner of said gatehouse; thence along the edge of the easterly granite wall of the Pawtucket Canal as follows:
NORTHERLY, more or less, a distance of about ninety-six feet (96),
WESTERLY, more or less, a distance of about three feet (3), and

SOUTHERLY, more or less, a distance of about thirty-eight feet (38) to a point on the easterly shoreline of aforesaid Pawtucket Canal; thence along said easterly shoreline

NORTHWESTERLY, more or less, a distance of about one thousand four hundred and sixty-four feet (1,464) to a point at the back edge of the easterly granite wall of said Pawtucket Canal; thence along said canal wall

NORTHWESTERLY, more or less, a distance of about twenty-six feet (26) to a point on the southerly line of Pawtucket Street; thence along said line of Pawtucket Street

N 50° -30' -01" E, a distance of about twenty-four feet (24) to an iron pin set at land now or formerly of the City of Lowell; thence along the westerly line of land of said City of Lowell as follows:

S 42° -57' -18" E, a distance of eighteen and 50/100 feet (18.50) to an iron pin set,

S 52° -22' -18" E, a distance of forty-five and 33/100 feet (45.33) to a drill hole set,

S 51° -03' -18" E, a distance of twenty-six and 92/100 feet (26.92) to an iron pin set,

S 45° -57' -08" E, a distance of ninety-nine and 63/100 feet (99.63) to an iron pin set,

S 27° -45' -08" E, a distance of nine and 13/100 feet (9.13) to a point,

S 23° -43' -08" E, a distance of one hundred sixty-six and 68/100 feet (166.68) to a drill hole set,

S 20° -16' -08" E, a distance of eighteen and 32/100 feet (18.32) to a drill hole set,

S 06° -36' -38" E, a distance of one hundred eight and 50/100 feet (108.50 to an iron pin set,

S 11° -40' -38" E, a distance of two hundred thirty-six and 01/100 feet (236.01) to an iron pin set,

S 17° -29' -58" E, a distance of thirty-six and 11/100 feet (36.11) to an iron pin set,

S 22° -11' -38" E, a distance of thirty-six and 39/100 feet (36.39) to an iron pin set,

S 30° -12' -38" E, a distance of one hundred thirty-one and 48/100 feet (131.48) to a drill hole in a stone bound found,

S 30° -12' -38" E, a distance of one hundred and 00/100 feet (100.00) to a drill hole in a stone bound found,

S 30° -12' -37" E, a distance of fifty-three and 52/100 feet (53.52) to a drill hole in a stone bound found,

SOUTHEASTERLY, more or less, by a curve to the left having a radius of two hundred twelve and 80/100 feet (212.80), an arc length of thirty-nine and 25/100 feet (39.25) to a drill hole in a stone bound found, and

S 40° -46' -41" E, a distance of sixty and 26/100 feet (60.26) to a point at land now or formerly of Thomas Riley; thence along the southwesterly line of Riley as follows:

S 40° -46' -41" E, a distance of ninety-one and 60/100 feet (91.60) to a drill hole in a stone bound found,

S 51° -27' -21" E, a distance of ninety-three and 41/100 feet (93.41) to a point, and

S 55° -19' -01" E, a distance of one hundred eight and 23/100 feet (108.23) to a P.K. nail set at Madonna Circle; thence along the westerly line of Madonna Circle

S 11° -00' -40" E, a distance of two hundred fifty-three and 76/100 feet (253.76) to the point of beginning.

PG 112
Parcel: 13B (con't)

Containing twenty-six thousand and two hundred (26,200) square feet of land, more or less.

PROPOSED DESCRIPTION OF LAND

PARCEL: 8-B

Beginning at a point at the southwesterly corner of the parcel on the northerly line of Broadway, said point being N 82°-56'-05" E, a distance of fifty-two and 74/100 feet (52.74) of a stone bound found on the northerly line of Broadway; thence by land now or formerly of the Proprietors of Locks and Canals by five (5) courses as follows:

N 03°-54'-52" W, a distance of fifty-one and 47/100 feet (51.47) to a point,

N 27°-06'-12" W, a distance of eighty-eight and 85/100 feet (88.85) to a point,

N 28°-42'-32" W, a distance of one hundred eighty and 03/100 feet (180.03) to a point,

N 30°-21'-02" W, a distance of ninety-eight and 70/100 feet (98.70) to a point, and

N 40°-51'-32" W, a distance of sixty three and 10/100 feet (63.10) to a point; thence by land now or formerly of the Commonwealth of Massachusetts by four courses as follows:

N 39°-26'-01" W, a distance of eleven and 26/100 feet (11.26) to a point,

N 41°-26'-13" W, a distance of sixty-five and 21/100 feet (65.21) to a point,

N 40°-55'-22" W, a distance of twenty-eight and 28/100 feet (28.28) to a point, and

N 38°-57'-44" W, a distance of six and 35/100 feet (6.35) to a point; thence continuing by land now or formerly of the Commonwealth of Massachusetts by (19) courses as follows:

N 40°-51'-40" W, a distance of fifty-nine and 18/100 feet (59.18) to a point,

N 37°-55'-55" W, a distance of thirty-one and 65/100 feet (31.65) to a point,

N 29°-43'-39" W, a distance of forty-seven and 04/100 feet (47.04) to a point,

N 25°-59'-51" W, a distance of eighteen and 34/100 feet (18.34) to a point,

N 26°-07'-46" W, a distance of one hundred forty-seven and 13/100 feet (147.13) to a point,

PARCEL 8-B (cont'd)

N 57°-28'-20" W, a distance of zero and 73/100 feet (0.73) to a point,

N 22°-42'-54" W, a distance of forty-eight and 48/100 feet (48.48) to a point,

N 21°-32'-50" W, a distance of twenty and 27/100 feet (20.27) to a point,

N 14°-11'-07" W, a distance of one hundred forty-one and 00/100 feet (141.00) to a point,

N 04°-08'-34" E, a distance of sixty and 21/100 feet (60.21) to a point,

N 10°-37'-49" W, a distance of sixty-six and 11/100 feet (66.11) to a point,

N 10°-13'-54" W, a distance of forty-two and 29/100 feet (42.29) to a point,

N 19°-09'-50" W, a distance of seventeen and 85/100 feet (17.85) to a point,

N 19°-17'-12" W, a distance of fifty-nine and 17/100 feet (59.17) to a point,

N 24°-17'-55" W, a distance of forty-three and 27/100 feet (43.27) to a point,

N 29°-51'-29" W, a distance of forty-five and 82/100 feet (45.82) to a point,

N 33°-34'-42" W, a distance of thirty-six and 78/100 feet (36.78) to a point,

N 40°-05'-46" W, a distance of eighty and 63/100 feet (80.63) to a point, and

N 40°-40'-59" W, a distance of fifty-eight and 49/100 feet (58.49) to a drill hole with lead plug and brass pin found at the intersection with the southerly line of Pawtucket Street; thence

N 50°-30'-01" E, along the southerly line of Pawtucket Street, a distance of about six feet (6) to the westerly face of a granite wall on the westerly side of the Pawtucket Canal; thence

SOUTHERLY, more or less, along the westerly face of the aforementioned wall a distance of about fourty-five feet (45) to the end of the wall; thence continuing

SOUTHERLY, more or less, along the westerly bank of the Pawtucket Canal a distance of one thousand two hundred and eighty-one feet (1281) to a granite wall; thence continuing

SOUTHERLY, more or less, along the westerly face of said granite wall a distance of about eighty-one feet (81) to a drill hole set along the westerly face of the granite wall at the top of a set of concrete steps; thence

S 27°-16'-45" E, along the westerly face of the aforementioned granite wall, a distance of forty and 79/100 feet (40.79) to the northerly

face of a building known as the Locking Gate House; thence

S 62°-43'-24" W, along the northerly face of the aforementioned building a distance of seven and 80/100 feet (7.80) to a building corner; thence

S 27°-16'-45" E, along the westerly face of the aforementioned building a distance of sixteen and 06/100 feet (16.06) to a building corner; thence

N 62°-43'-24" E, along the southerly face of the aforementioned building a distance of about six feet (6) to the westerly face of a granite wall on the westerly side of the Pawtucket Canal; thence

SOUTHERLY, more or less, along the aforementioned wall a distance of about fifty-five-feet (55) to the northwesterly corner of a building known as the Francis Gate House; thence

S 27°-26'-58" E, along the westerly face of the Francis Gate House a distance of thirteen and 41/100 feet (13.41) to the southwesterly corner of the Francis Gate House; thence by the westerly face of a granite wall on the westerly side of the Pawtucket Canal by five (5) courses as follows:

SOUTHERLY, about twelve feet (12),

WESTERLY, about thirteen feet (13),

SOUTHERLY, about three feet (3),

EASTERLY, about sixteen feet (16), and

SOUTHERLY, about six and 4/10 feet (6.4) to an iron pin set at the westerly face of said wall; thence continuing

SOUTHERLY, more or less, along the westerly face of the aforementioned wall about fifty-one feet (51) to an angle point in the wall; thence continuing

SOUTHERLY, more or less, along said wall a distance of about twenty-five feet (25) to an iron pin set at the westerly face of said wall, said iron pin being seventy-five and 37/100 feet (75.37) on a bearing of S 21°-00'-01" E, from the last mentioned iron pin; thence

SOUTHWESTERLY, more or less, along the westerly face of the aforementioned granite wall a distance of about twenty-eight feet (28) to the northerly line of Broadway; thence

S 82°-56'-05" W, along Broadway a distance of about twenty-two feet (22) to the point of beginning.

Containing thirty-seven thousand five hundred square feet (37,500) of land, more or less.

PROPOSED DESCRIPTION OF LAND

PARCEL: 8-C

Beginning at an iron pin set at the most northerly corner of the parcel, said pin being set at the back edge of the granite wall of the Pawtucket Canal; thence running along the exposed back edge of said granite wall

S 70°-45'-09" E, a distance of fifty-one and 24/100 feet (51.24) to an iron pin set; thence continuing along the exposed back edge of said wall by three (3) courses as follows:

SOUTHEASTERLY, more or less, a distance of about thirty-seven feet (37) to a chisel-cut set in the wall, said chisel-cut bearing S 45°-23'-13" E, and being thirty-four and 88/100 feet (34.88) distant from the last point described,

SOUTHWESTERLY, more or less, a distance of about three feet (3), and

SOUTHERLY, more or less, a distance of about four feet to the most westerly corner of the Hydraulic Gate House, said corner bearing S 07°-38'-47" W, and being five and 59/100 feet distant from the last mentioned chisel-cut; thence along the southwesterly face of the Hydraulic Gate House

S 20°-48'-37" E, a distance of nineteen and 39/100 feet (19.39) to the most southerly corner of said Gate House; thence running along the southerly face of the Hydraulic Gate House

N 69°-11'-23" E, a distance of four feet, more or less, to a point; thence running perpendicular to the last mentioned course

SOUTHERLY, more or less, a distance of about thirteen feet (13) to a point on the westerly edge of a stone wall; thence running along the edge of said wall as follows:

SOUTHWESTERLY, more or less, a distance of about twenty-two feet (22) to a point,

SOUTHEASTERLY, more or less, a distance of about three feet (3) to a point,

NORTHEASTERLY, more or less, a distance of about eighteen feet (18) to a point, and

SOUTHERLY, more or less, a distance of about forty-one feet to a drill hole set at the back of exposed edge of said wall, said drill hole bearing S 13°-10'- 24" E, and being fifty-eight and 36/100 feet (58.36) distant from the aforementioned southwesterly corner of the Hydraulic Gate House; thence continuing along the back edge of the exposed wall as follows:

S 19°-32'-24" W, a distance of twenty-three and 95/100 feet (23.95) to an iron pin set,

PG 118

S 88°-10'-35" W, a distance of eleven and 14/100 feet (11.14) to an iron pin set,

N 29°-55'-13" W, a distance of thirteen and 01/100 feet (13.01) to an iron pin set,

N 35°-19'-04" W, a distance of twelve and 82/100 feet (12.82) to an iron pin set, and

N 11°-33'-48" W, a distance of eighteen and 18/100 feet (18.18) to a drill hole set; thence continuing along the edge of exposed wall:

NORTHEASTERLY, more or less, a distance of about fourteen feet to a point,

NORTHWESTERLY, more or less, a distance of about three feet (3) to a point,

SOUTHWESTERLY, more or less, a distance of about fourteen feet (14) to a point,

NORTHWESTERLY, more or less, a distance of about twelve feet to the southeasterly corner of the Francis Gate House, said corner bearing N 36°-56'-54" W, and being fifteen and 26/100 feet (15.26) distant from the last mentioned drill hole; thence running along the northeasterly face of the Francis Gate House

N 27°-26'-58" W, a distance of thirteen and 41/100 feet (13.41) to the northeasterly corner thereof; thence running along the back of the exposed granite wall

N 17°-56'-25" W, a distance of nine and 09/100 feet (9.09) to a drill hole set in the bottom step of some granite steps; thence continuing along the back edge of the wall

NORTHWESTERLY, more or less, a distance of about thirty-two feet (32) to a point on the southerly wall of the Locking Gate House; thence running along the face of the north end of the Gate House as follows:

N 62°-43'-24" E, a distance of about seven feet (7) to the northeasterly corner of the Gate House,

N 27°-16'-45" W, a distance of sixteen and 06/100 feet (16.06) to the northerly corner of the Gate House,

S 62°-43'-24" W, a distance of about eight and 7/10 feet (8.7) to a point on the northerly face of the Locking Gate House, said point being at the back of the exposed granite wall as hereinbefore mentioned; thence running along the back of said wall

NORTHWESTERLY, more or less, a distance of about zero and 7/10 feet (0.7) to a drill hole set, said drill hole bearing S 66°-57'-39" W, and being eight and 71/100 feet (8.71) distant from the aforementioned northerly corner of the Locking Gate House; thence continuing along the back edge of said wall

N 22°-50'-38" W, a distance of thirty-two and 98/100 feet (32.98) to the point of beginning.

PARCEL B-C (cont'd)

Containing five thousand six hundred and sixty square feet of land, more or less.

N 62°-43'-24" E, along the southerly face of the aforementioned building a distance of about six feet (6) to the westerly face of a granite wall on the westerly side of the Pawtucket Canal; thence

SOUTHERLY, more or less, along the aforementioned wall a distance of about fifty-five-feet (55) to the northwesterly corner of a building known as the Francis Gate House; thence

S 27°-26'-58" E, along the westerly face of the Francis Gate House a distance of thirteen and 41/100 feet (13.41) to the southwesterly corner of the Francis Gate House; thence by the westerly face of a granite wall on the westerly side of the Pawtucket Canal by five (5) courses as follows:

SOUTHERLY, about twelve feet (12),

WESTERLY, about thirteen feet (13),

SOUTHERLY, about three feet (3),

EASTERLY, about sixteen feet (16), and

SOUTHERLY, about six and 4/10 feet (6.4) to an iron pin set at the westerly face of said wall; thence continuing

SOUTHERLY, more or less, along the westerly face of the aforementioned wall about fifty-one feet (51) to an angle point in the wall; thence continuing

SOUTHERLY, more or less, along said wall a distance of about twenty-five feet (25) to an iron pin set at the westerly face of said wall, said iron pin being seventy-five and 37/100 feet (75.37) on a bearing of S 21°-00'-01" E, from the last mentioned iron pin; thence

PARCEL: Guard Locks - Lock Chamber

Northeasterly, N 30° - 24'- 34"E, a distance of sixty two and 37/100 feet (62.37) to an iron pin set,

S 88°-10'-35" W, a distance of eleven and 14/100 feet (11.14) to an iron pin set,

N 29°-55'-13" W, a distance of thirteen and 01/100 feet (13.01) to an iron pin set,

N 35°-19'-04" W, a distance of twelve and 82/100 feet (12.82) to an iron pin set, and

N 11°-33'-48" W, a distance of eighteen and 18/100 feet (18.18) to a drill hole set; thence continuing along the edge of exposed wall:

NORTHEASTERLY, more or less, a distance of about fourteen feet to a point,

NORTHWESTERLY, more or less, a distance of about three feet (3) to a point,

SOUTHWESTERLY, more or less, a distance of about fourteen feet (14) to a point,

NORTHWESTERLY, more or less, a distance of about twelve feet to the southeasterly corner of the Francis Gate House, said corner bearing N 36°-56'-54" W, and being fifteen and 26/100 feet (15.26) distant from the last mentioned drill hole; thence running along the northeasterly face of the Francis Gate House

N 27°-26'-58" W, a distance of thirteen and 41/100 feet (13.41) to the northeasterly corner thereof; thence running along the back of the exposed granite wall

N 17°-56'-25" W, a distance of nine and 09/100 feet (9.09) to a drill hole set in the bottom step of some granite steps; thence continuing along the back edge of the wall

NORTHWESTERLY, more or less, a distance of about thirty-two feet (32) to a point on the southerly wall of the Locking Gate House; thence running along the face of the north end of the Gate House as follows:

N 62°-43'-24" E, a distance of about seven feet (7) to the northeasterly corner of the Gate House,

N 27°-16'-45" W, a distance of sixteen and 06/100 feet (16.06) to the northerly corner of the Gate House,

S 62°-43'-24" W, a distance of about eight and 7/10 feet (8.7) to a point on the northerly face of the Locking Gate House, said point being at the back of the exposed granite wall as hereinbefore mentioned; thence running along the back of said wall

PARCEL: Guard Locks - Lock Chamber

NORTHWESTERLY, more or less, a distance of about zero and 7/10 feet (0.7) to a drill hole set, said drill hole bearing S 66°-57'-39" W, and being eight and 71/100 feet (8.71) distant from the aforementioned northerly corner of the Locking Gate House; thence continuing along the back edge of said wall

N 22°-50'-38" W, a distance of thirty-two and 98/100 feet (32.98) to a point, thence

Westerly, S 73° - 44' - 18"W, a distance of thirty eight and 05/100 (38.05) to the point of begining.

Containing five thousand nine hundred and eighty four square feet (5,984) of land, more or less.

PROPOSED DESCRIPTION OF LAND

PARCEL: SWAMP LOCKS - LOCK CHAMBER

Beginning at a cross-cut set at the most westerly corner of the parcel, said cross-cut being at the back edge of the southerly granite wall of the Pawtucket Canal and being on the northerly line of land of Parcel CB-I as hereinbefore described; thence crossing the headwaters of the Swamp Locks and running

N 60°-11'-35" E, a distance of forty-five and 57/100 feet (45.57) to a cut set on the northerly face of a concrete buttress; thence along the northerly face of said buttress

N 86°-14'-27" E, a distance of seven and 43/100 feet (7.43) to the westerly face of the Swamp Locks Gatehouse; thence running along the walls of said gatehouse:

S 03°-45'-33" E, a distance of four and 26/100 feet (4.26) to a corner,

N 86°-14'-27" E, a distance of twelve and 42/100 feet (12.42) to a corner, and

N 03°-45'33" W, a distance of one and 17/100 feet (1.17) to a point on the easterly wall of said Swamp Locks Gatehouse; continuing,

N 03°-45'33" W, a distance of eighteen and 96/100 feet (18.96) to a point at the northerly face of the southerly granite wall of the Lower Pawtucket Canal; thence running along said granite wall as follows:

N 85°-34'-20" E, a distance of forty-six and 21/100 feet (46.21) to a cut set in the face of said wall,

N 84°-43'-16" E, a distance of forty-three and 12/100 feet (43.12) to a cut set in the face of said wall, and

N 89°-50'-16" E, a distance of twenty and 87/100 feet (20.87) to a cut set in the face of said wall; thence running along the northerly face of the southerly granite wall of the Lower Pawtucket Canal and thence crossing a twenty foot passageway

N 86°-13'-40" E, a distance of sixty-six and 78/100 feet (66.78) to a point on the easterly line of said twenty foot passageway; thence running along the easterly line of said passageway

N 09°-30'-31" W, a distance of three and 95/100 feet (3.95) to the southerly shoreline of the Lower Pawtucket Canal; thence running along said southerly shoreline as follows:

N 85°-27'-15" E, a distance of forty-one and 46/100 feet (41.46) to a point,

N 88°-55'-33" E, a distance of eighty and 01/100 feet (80.01) to a point, and

S 06°-40'-48" E, a distance of eleven and 18/100 feet (11.18) to a point at the bottom of the Swamp Locks Lower Lock Chamber; thence running along said Lower Lock Chamber

S 84°-08'-49" W, a distance of forty-eight and 05/100 feet (48.05) to a point; thence running, as follows:

S 00°-25'-22" E, a distance of twenty-seven and 89/100 feet (27.89) to a point on the northerly line of land now or formerly of the Pellon Corporation; thence alng the line of said Pellon Corporation

S 77°-16'-35" W, a distance of sixty-six and 89/100 feet (66.89) to a point on the easterly line of a twenty foot passageway leading to Jackson Street; thence along the easterly line of said passageway

N 13°-10'-56" W, a distance of eleven and 82/100 feet (11.82) to a point at the southerly wall of the Swamp Locks Lower Lock Chamber; thence along the southerly wall of the Swamp Locks Lower Lock Chamber as follows:

S 81°-09'-40" W, a distance of fifty-two and 56/100 feet (52.56) to a drill hole set in the face of a concrete wall, and

N 01°-48'-53" W, a distance of seven and 55/100 feet (7.55) to an iron pin set at the back edge of the southerly granite wall of the Swamp Locks Upper Chamber; thence running along the back edge of said granite wall as follows:

S 85°-46'-53" W, a distance of one hundred thirty-nine and 78/100 feet (139.78)

S 87°-04'-42" W, a distance of forty-nine and 47/100 feet (49.47) to the point of beginning.

Containing eleven thousand six hundred and eighty five square feet (11,685), of land, more or less.

PROPOSED DESCRIPTION OF LAND

PARCEL: CB-G

Beginning at a drill hole set at the most southeasterly corner of the parcel, said drill hole being at the back edge of the northerly granite wall of the Lower Pawtucket Canal and the westerly wall of a wasteway appurtenant thereto; thence along the back edge of said granite canal wall:

S 77° -29' -58" W, a distance of one hundred eighty-four and 15/100 feet (184.15) to an x-cut set, and

S 77° -30' -59" W, a distance of one hundred sixty-nine and 44/100 feet (169.44) to a point at the inlet of an abandoned penstock; thence continuing along the back edge of said canal wall, more or less, and running under a concrete slab deck erected over a portion of the canal

S 88° -10' -10" W, a distance of three hundred fifty-seven and 82/100 feet (357.82) to a drill hole set in the top of a concrete wall; thence

N 76° -48' -05" W, a distance of twenty-eight and 87/100 feet (28.87) to a P.K. nail set in the pavement of the margin roadway; thence

N 64° -01' -21" W, a distance of sixty-one and 75/100 feet (61.75) to a P.K. nail set; thence

S 79° -49' 52" W, a distance of forty-one and 03/100 feet (41.03) to a drill hole set at the back edge of the concrete wall of the Pawtucket Canal; thence along the back edge of said concrete wall as follows:

N 73° -14' -07" W, a distance of nine and 54/100 feet (9.54) to a point,

N 51° -46' -40" W, a distance of seventeen and 24/100 feet (17.24) to a point, and

NORTHWESTERLY, more or less, by a curve in said wall to an iron pin set, said pin bearing N 22° -38' -49" W, and being five and 64/100 feet (5.64) distant from the point last mentioned; thence

N 43° -25' -34" E, a distance of sixty-seven and 95/100 feet (67.95) to a point; thence

N 08° -17' -03" W, a distance of six and 00/100 feet (6.00) to a drill hole set at the back edge of the southerly granite wall of the Merrimack Canal; thence along said granite canal wall

N 42° -20' -18" E, a distance of one hundred two and 32/100 feet (102.32) to a P.K. nail set, and

N 36° -47' -04" E, a distance of thirty-one and 41/100 feet (31.41) to an iron pin set; thence running under a bridge over said Merrimack Canal

N 43° -41' -11" E, a distance of sixty-three and 21/100 feet (63.21) to a point; thence

Parcel: CB-3 (con()

S 46° -18' -49" E, a distance of eleven and 59/100 feet (11.59) to a point; thence in part by the back edge of the granite wall

N 43° -30' -36" E, a distance of one hundred four and 47/100 feet (104.47, to an iron pin set; thence crossing the inlet of an abandoned penstock

N 46° -43' -29" E, a distance of thirty-eight and 32/100 feet (38.32) to an iron pin set; thence along the back edge of a granite wall as follow

N 41° -47' -54" E, a distance of seventy-two and 39/100 feet (72.39) to a point, and

N 44° -05' -17" E, a distance of ninety-five and 94/100 feet (95.94) to an iron pin set; thence running along the shoreline of the Merrimack Canal more or less, as follows:

N 25° -13' -45" E, a distance of thirty and 15/100 feet (30.15) to an iron pin set,

N 34° -16' -58" E, a distance of twenty-two and 39/100 feet (22.39) to an x-cut set, and

S 48° -14' -10" E, a distance of twelve and 75/100 feet (12.75) to an iron pin set at the back edge of a granite wall; thence along the back edge of said wall

N 43° -46' -07" E, a distance of one hundred twenty-six and 24/100 feet (126.24) to an iron pin set, and still by the edge of said wall

N 43° -46' -07" E, a distance of twenty-four and 02/100 feet (24.02) to the end thereof; thence

N 22° -32' -24" E, a distance of twenty-three and 98/100 feet (23.98) to the back corner of a concrete wall; thence along the back edge of said wall as follows:

N 25° -42' -52" E, a distance of thirteen and 29/100 feet (13.29) to a point,

N 49° -58' -52" E, a distance of twenty-one and 23/100 feet (21.23) to a point, and

N 67° -34' -51" E, a distance of twenty-five and 07/100 feet (25.07) to a point on the edge of said wall at land now or formerly of C.W.S. Associates Trust; thence by land of C.W.S. Associates and land of the Commonwealth of Massachusetts as follows:

S 46° -38' -52" E, a distance of nine and 00/100 feet (9.00) to a point, and

S 43° -41' -11" W, a distance of six hundred eighteen and 92/100 feet (618.92) to a drill hole in a concrete bound found at land now or formerly of the Pellon Corporation; thence by land of said Pellon Corporation as follows:

S 43° -41' -03" W, a distance of twenty-two and 75/100 feet (22.75) to a point,

S 43° -07' -46" W, a distance of sixty-five and 21/100 feet (65.21) to

S 41° -58' -46" W, a distance of one hundred and 40/100 feet (100.40) to a point,

S 48° -01' -14" E, a distance of fourteen and 54/100 feet (14.54) to a point,

N 89° -49' -46" E, a distance of thirty-seven and 98/100 feet (37.98) to a point,

S 62° -42' -14" E, a distance of forty-eight and 00/100 feet (48.00) to a point,

S 74° -47' -14" E, a distance of twenty-seven and 00/100 feet (27.00) to a point,

N 88° -10' -46" E, a distance of three hundred fifty-six and 93/100 feet (356.93) to a P.K. nail set, and

N 77° -31' -26" E, a distance of three hundred fifty-three and 06/100 feet (353.06) to a drill hole set at the back edge of the westerly granite wall of a wasteway; thence along the back edge of said wall

S 12° -33' -54" E, a distance of eighteen and 50/100 feet (18.50) to the point of beginning.

Containing twenty-five thousand two hundred and nine (25,209) square feet of land, more or less.

PROPOSED DESCRIPTION OF LAND

PARCEL: LOWER LOCKS LOCK CHAMBERS

Beginning at the most westerly corner of the parcel, said corner being a point on the northerly line of Parcel CB-H as hereinbefore described and bearing S 85° -57' 30" E, and being forty-nine and 55/100 feet (49.55) distant from a drill hole set in the southwesterly end of a concrete wall; thence running to a point on the northerly side of the Lower Locks

N 12° -49' -10" E, a distance of twenty-three and 64/100 feet (23.64); thence running along the outer edge of the granite blocks

S 82° -56' -24" E, a distance of seventeen and 44/100 feet (17.44) to a point on the southerly prolongation of the westerly line of the Lower Locks Gate House; thence

N 06° -25' -46" E, a distance of one and 49/100 feet (1.49) to the southwesterly corner of the Lower Locks Gate House as hereinafter described; thence along the southerly face of said Gate House

S 83° -34' -14" E, a distance of seven and 50/100 feet (7.50) to the southeast corner of the Lower Locks Gate House; thence along the easterly wall of said Gate House

N 06° -25' -46" E, a distance of four and 76/100 feet (4.76) to a point; thence along the northerly edge of the concrete capped wall of the Lower Locks

S 83° -18' -52" E, a distance of one hundred twenty-six and 25/100 feet (126.25) to a point; thence along the northerly top edge of granite of the Lower Locks by three (3) courses as follows:

N 89° -40' -25" E, a distance of nine and 86/100 feet (9.86) to a point,

S 82° -53' -58" E, a distance of ninety-eight and 75/100 feet (98.75) to a point, and

N 80° - 11' -21" E, a distance of eleven and 35/100 feet to a point at the base of the granite blocks of the Lower Locks; thence running along the base of said blocks

S 06° -01' -39" W, a distance of thirty-eight and 00/100 feet (38.00) to an iron pin set at the base of the last granite stone on the southeasterly end of the Lower Locks, said iron pin being at an angle in the northerly line of Parcel CB-H as hereinbefore described; thence running along the southerly line of the Lower Locks, being the northerly line of Parcel CB-H, by four (4) courses as follows:

N 83° -10' -03" W, a distance of one hundred thirty-six and 39/100 feet (136.39) to a drill hole set in granite,

PARCEL: LOWER LOCKS LOCK CHAMBERS (CONT.)

N 83° -28' -56" W, a distance of one hundred ten and 00/100 feet (110.00) to an iron pin set,

N 44° -46' -55" W, a distance of eight and 86/100 feet (8.86) to an x-cut set in granite, and

N 85° -57' -30" W, a distance of twenty and 24/100 feet (20.24) to the point of beginning.

Containing nine thousand one hundred and twenty-seven square feet of land, more or less.

PROPOSED DESCRIPTION OF LAND

PARCEL: 5345A

Beginning at the southwesterly corner of the parcel, said corner bearing N 12° -38' -52" W, and being twenty-three and 00/100 feet (23.00) distant from the northerly line of Jackson Street; thence running along the easterly line of land now or formerly of James T. Lichoulas, trustee of Appleton Trust

N 12° -38' -52" W, a distance of ten and 91/100 feet (10.91) to a cut set at the face of a concrete wall; thence running along the southerly line of land now or formerly of the Proprietors of Locks and Canals and along said wall

N 84° -56' -46" E, a distance of forty-eight and 75/100 feet (48.75) to a drill hole set at the corner of said wall; thence running along the easterly line of land now or formerly of the Proprietors of Locks and Canals

N 02° -30' -39" E, a distance of seventeen and 68/100 feet (17.68) to a point at the Hamilton Canal; thence running along the southerly side of the Hamilton Canal

N 86° -56' -46" E, a distance of sixty-four and 37/100 feet (64.37) to a point on the northwesterly line of Parcel 5345C as hereinafter described; thence running along said northwesterly line of Parcel 5345C by two (2) courses as follows:

SOUTHWESTERLY, more or less, by a curve to the right having a radius of one hundred forty-two and 00/100 feet (142.00), an arc length of eighteen and 55/100 feet (18.55) to a point of compound curvature, and

SOUTHWESTERLY, more or less, by a curve to the right having a radius of ninety-eight and 00/100 feet (98.00), an arc length of thirty-four and 00/100 feet (34.00) to a point at the southeasterly corner of Parcel 5345B as hereinafter described; thence running along the easterly line of Parcel 5345B

N 12° -38' -52" W, a distance of five and 50/100 feet (5.50) to a point; thence running along the northerly line of Parcel 5345B, said line being twenty-three and 00/100 feet (23.00) distant from and parallel with the northerly line of Jackson Street

S 77° -21' -08" W, a distance of sixty-seven and 00/100 feet (67.00) to the point of beginning.

Containing one thousand four hundred and thirty-eight square feet (1,438) of land, more or less.

Appendix D – 1995 *Grant of Easement*

GRANT OF EASEMENT

The COMMONWEALTH OF MASSACHUSETTS, acting by and through its Division of Capital Planning and Operations ("Grantor"), notwithstanding the provisions of sections 40E through 40J, inclusive, of Chapter 7 of the General Laws, in accordance with Chapter 149 of the Acts of 1992, for nominal consideration paid, does hereby grant to the UNITED STATES OF AMERICA, acting by and through the United States Department of the Interior, having a usual place of business at 222 Merrimack Street, Lowell, Massachusetts, 01852, ("Grantee") a perpetual easement, in common with others and subject to the terms and conditions of this grant, over, on and in the property known as the Lowell Heritage State Park in Lowell, Massachusetts (the "Property") in the locations described on Exhibit A attached hereto for the purposes specified herein:

Easement Area I = Tracts 104-26, 107-07, 107-15, 107-22, 107-23, 107-24, 107-25, 107-26, 107-27, 107-28, 107-29, 110-02, 111-09, 111-22, 111-23, and 111-24

GRANTEE, its successors and assigns, shall have the right, in conjunction with others, to use the premises described herein for all purposes consistent with the Act establishing the Lowell National Historical Park, Public Law 95-290, as amended, (16 U.S.C., Sections 410cc et seq.), hereinafter referred to as the Act, and consistent with Chapter 149 of the Acts of 1992, hereinafter referred to as the Special Act, which purposes shall include: facilitation and provision of a continuous public pedestrian walkway along the Western canal, construction and maintenance of improvements, which improvements include but shall not be limited to: walkway surface at the edge of the Western Canal, decking, lighting, railing, benches, landscaping, signs and public art.

Easement Area II = Tract 107-35

GRANTEE, its successors and assigns, shall have the right, in conjunction with others, to use the premises described herein for all purposes consistent with the Act and consistent with the Special Act, which purposes shall include: facilitation and provision of a continuous public pedestrian walkway and linear park along the Western canal, construction and maintenance of improvements, which improvements include but shall not be limited to: walkway surface at the edge of the Western Canal, decking, lighting, aerial and/or buried telecommunications cable, benches, landscaping, signs and public art.

07/06/95 PLAN BOOK: 188 PAGE: 145

07/06/95 03:06:09 28204 82.00 6

Easement Are III = Tracts 110-03, 110-06, 110-07, 110-09, 110-14, 110-20, 111-26

GRANTEE, its successors and assigns, shall have the right, in conjunction with others, to use the premises described herein for all purposes consistent with the Act and consistent with the Special Act, which purposes shall include: facilitation and provision of a continuous public pedestrian walkway and linear park along the Pawtucket canal, construction and maintenance of improvements, which improvements include but shall not be limited to: walkway surface at the edge of the Pawtucket Canal, decking, lighting, railing, benches, landscaping, signs and public art.

Easement Area IV = Tracts 105-09, Tract 105-10, Tract 105-14, Tract 105-15

GRANTEE, its successors and assigns, shall have the right, in conjunction with others, to use the premises described herein for all purposes consistent with the Act and consistent with the Special Act, which purposes shall include: facilitation and provision of a continuous public pedestrian walkway and linear park along the junction of the Pawtucket Canal, Merrimack River and the Northern Canal, maintenance and operation of the Gatekeeper's House, so-called, and of the Blacksmith Shop, so-called, construction and maintenance of improvements, which improvements include but shall not be limited to: maintenance and renovation of the Gatekeeper's House and the Blacksmith Shop, walkway surface at the edge of the Pawtucket Canal, the Northern Canal and the Merrimack River, decking, lighting railing, benches, landscaping, signs and public art.

Easement Area V = Tract 111-17

GRANTEE, its successors and assigns, shall have the right, in conjunction with others, to use the premises described herein for all purposes consistent with the Act and consistent with the Special Act, which purposes shall include: facilitation and provision of a continuous public pedestrian walkway and linear park along the Hamilton Canal, construction and maintenance of improvements, which improvements include but shall not be limited to: walkway surface at the edge of the Hamilton Canal, decking, lighting, railing, benches, landscaping, signs and public art.

Easement Area VI = Tract 107-21

GRANTEE, its successors and assigns, shall have the right, in conjunction with others, to use the premises described herein for all purposes consistent with the Act and consistent with the Special Act, which purposes shall

include: facilitation and provision of a continuous public pedestrian walkway along the Eastern Canal and Merrimack Canal Wasteway, construction and maintenance of improvements, which improvements include but shall not be limited to: walkway surface at the edge of the Eastern Canal and Merrimack Canal Wasteway, decking, lighting, railing, benches, landscaping, signs and public art.

Easement Area VII = Tract 107-39

GRANTEE, its successors and assigns, shall have the right, in conjunction with others, to use the premises described herein for all purposes consistent with the Act and consistent with the Special Act, which purposes shall include: facilitation and provision of a continuous public pedestrian walkway along the Northern Canal, construction and maintenance of improvements, which improvements include but shall not be limited to: walkway surface at the edge of the canal, decking, lighting, railing, benches, landscaping, signs and public art.

Easement Area VIII = Tracts 103-11, 105-13, 107-13, 107-38, 107-40, 108-21, 111-32, 111-33, 111-34, 112-01, 112-04

GRANTEE, its successors and assigns, shall have the right, in conjunction with others, to use the premises described herein for any and all purposes consistent with the Act and consistent with the Special Act, which purposes shall include, but not be limited to: conducting land and canal tours, running interpretive programs and the maintenance, improvement and restoration of Gatehouses and support structures, Dams and Lock Chambers.

The rights conveyed hereunder are conveyed subject to all matters of record at the Middlesex County Registry of Deeds.

All work performed by Grantee, its successors and assigns, pursuant to this easement shall at all times be performed in accordance with all applicable federal laws, statutes, and regulations including, but not limited to, 40 U.S.C. Section 619.

By its acceptance of this easement, the Grantee agrees that its liability relating to this easement shall be governed by the Federal Tort Claims Act, 28 U.S.C. Sections 2671 et seq.

By its acceptance of this easement, the Grantee agrees that its exercise of the Grantee's rights hereunder shall not interfere with the Grantor's use and operation of the Property as a state park or with the use, maintenance, or

operation for hydroelectric power production by Boott Hydropower, Inc., their successors and assigns.

In the event that the easement granted herein ceases to be used in connection with the purposes described herein, then the Grantee's interest in such easement area shall revert to the Grantor.

IN WITNESS WHEREOF, the Commonwealth of Massachusetts has caused these presents to be signed, sealed, acknowledged and delivered in its name and on its behalf by the undersigned, as the duly appointed and authorized Commissioner of the Division of Capital Planning and Operations on this 1st day of June, 1995.

Lark Jurev Palermo
Lark Jurev Palermo,
Commissioner

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 999 square feet, more or less

Interest: Easement

Date: February 3, 1994

TRACT 103-11

A certain parcel of land with buildings, structures and fixtures, thereon, commonly known as the Northern Canal Waste Gate House, located in Lowell, Middlesex County, Massachusetts along the Northern Canal, so called, and further bounded and described as follows:

Beginning at a point on the southwesterly wall of the Northern Canal Waste Gate House, said point being the northeasterly corner of the Northern Canal Walkway, as shown on the plan hereinafter described; thence running by the northerly end of said walkway and by the Merrimack River

N 29° 58' 11" W, a distance of 13.58 feet to the southwest corner of the gate house; thence along the wall of the gate house as follows:

N 60° 01' 49" E, by the Merrimack River, a distance of 67.39 feet to a corner,

S 29° 58' 11" E, a distance of 14.82 feet to a corner at the Northern Canal, and, along said canal

S 60° 01' 49" W, a distance of 67.39 feet to the southeast corner of the gate house; thence along the southwesterly wall of the gate house

N 29° 58' 11" W, a distance of 1.4 feet to the point of beginning.

Containing 999 square feet of land, more or less.

Being shown as the Northern Canal Waste Gate House on sheet 23 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 5,844 square feet, more or less

Interest: Easement

Date: January 13, 1994

TRACT 104-26

A certain parcel of land situated in Lowell, Middlesex County, Massachusetts, along the Western Canal, so called, and being further bounded and described as follows:

Beginning at an iron pin set at the northeast corner of Suffolk Street and Perkins Street; thence along the northeasterly line of Perkins Street

N 41° 40' 50" W, a distance of 72.52 feet to a PK nail set at land now or formerly of George W. McQuade; thence along the southeasterly line of McQuade

N 48° 19' 10" E, a distance of 20.02 feet to PK nail set at the back edge of the southwesterly granite wall of the Lawrence Canal; thence along said canal wall:

S 43° 07' 56" E, a distance of 21. 56 feet to a chain link fence post,

S 43° 07' 56" E, a distance of 13.81 feet to a chain link fence post,

S 40° 33' 30" E, a distance of 40.14 feet to a chain link fence post, and

S 12° 24' 37" E, a distance of 8.32 feet to a chain link fence post at the Lower Level of the Western Canal; thence along the back edge of the northwesterly granite wall of said Lower Level of the Western Canal as follows:

S 25° 02' 30" W, a distance of 8.53 feet to a chain link fence post,

S 47° 47' 35" W, a distance of 35.25 feet to a chain link fence post,

S 47° 19' 23" W, a distance of 32.29 feet to an iron pin set,

S 49° 49' 54" W, a distance of 85.90 feet to an iron pin set,

S 47° 51' 11" W, a distance of 124.42 feet to a point,

S 65° 28' 17" W, a distance of 16.37 feet to an iron pin set, and

S 49° 24' 19" W, a distance of 48.63 feet to a drill hole set on the northeasterly line of a thirty foot right-of-way; thence along said right of way

N 41° 36' 20" W, a distance of 7.47 feet to a point on the southeasterly line of Suffolk Street; thence along said line of Suffolk Street

N 48° 19' 10" E, a distance of 333.85 feet to the point of beginning

Containing 5,844 square feet of land, more or less.

Being shown as Parcel CB-E, Lot C on sheet 25 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 15,957 square feet, more or less

Interest: Easement

Date: February 1, 1994

TRACT 105-09

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Northern Canal and the Merrimack River, so called, and known and numbered as 23.1 School Street and further bounded and described as follows:

Beginning at a drill hole set on the southwesterly line of School Street, said drill hole being at the northwesterly corner of land now or formerly of the Commonwealth of Massachusetts by two courses as follows:

S 42° 50' 42" W, a distance of 76.30 feet to an iron pin set, and

S 24° 14' 32" W, a distance of 72.91 feet to an iron pin set; thence along the southwesterly line of land of the Commonwealth of Massachusetts

S 61° 39' 08" E, a distance of 97.41 feet to a point on the northwesterly line of land now or formerly of the American Red Cross; thence along the northwesterly line of land of said American Red Cross and now or formerly of Flago Realty Corporation

S 40° 13' 24" W, a distance of 220.81 feet to an x-cut in a stone bound found at land now or formerly of Irene Desmarais; thence along the northeasterly line of said land now or formerly of said Desmarais as follows:

N 23° 03' 25" W, a distance of 42.34 feet to a point, and

N 19° 33' 29" E, a distance of 22 feet to a drill hole set in the granite retaining wall of the Merrimack River; thence along the Merrimack River by said retaining wall:

N 48° 01' 43" W, a distance of 10 feet to a drill hole set,

N 23° 55' 13" E, a distance of 165.57 feet to a point,

N 24° 14' 32" E, a distance of 74.06 feet to a drill hole set, and

N 42° 50' 42" E, a distance of 77.48 feet to a drill hole set on the southwesterly line of School Street; thence along said line of School Street

S 46° 51' 34" E, a distance of 7 feet to the point of beginning.

Containing 15,957 square feet of land, more or less.

Being shown as Parcel 29, Lot 2 on sheet 20 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

EXHIBIT A

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 13,678 square feet, more or less

Interest: Easement

Date: February 1, 1994

TRACT 105-10

A certain parcel of land, with the buildings thereon, located in Lowell, Middlesex County, Massachusetts along the Northern Canal and the Merrimack River, so called, and known and numbered as 23 School Street and further bounded and described as follows:

Beginning at the Easterly corner of the premises at a point in the Southwesterly line of School Street in said Lowell, where the Southeasterly face of a retaining wall intersects said School Street, which point is distant 199.75 feet Northerly from a drill hole in a stone bound set in the line of said School Street;

Thence, S 45° 20' W by the said face of the said wall and by land now or formerly of Harold F. Harrington et. als. and land now or formerly of the American National Red Cross, 111 feet, to a point;

Thence, at an angle S 56° 3' W still by said last named land and said wall, 12.46 feet to a point;

Thence, N 46° 2' 30" W by other land now or formerly of Proprietors of the Locks and Canals on Merrimack River, 97.36 feet to a stake at still other land now or formerly of said Proprietors of Locks and Canals;

Thence, N 39° 51' 40" E 72.91 feet to a point;

Thence, at an angle of 58° 27' 50" E still by said Proprietors of Locks and Canals; land and in part by the Southeasterly face of another retaining wall 76.30 feet to said School Street;

Thence, S 31° 14' 30" E by said School Street 91.78 feet to the point of beginning.

Containing 13,678 square feet of land, more or less.

Being shown on a plan of land entitled "Plan of Land in Lowell, Mass. for Prop. of Locks and Canals, July 5, 1960, Dana F. Perkins & Sons, Inc., C.E.'s and Surveyors," which plan is recorded with the Middlesex Northern District Registry of Deeds, Plan Book 93, Plan 59A.

Also being shown as Parcel 29, Lot 1 on sheet 20 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with said Registry of Deeds at Plan Book 157, Plan 69.

Being the same premises conveyed to the Commonwealth of Massachusetts by deed of Paul J. Desmarais and Lorraine L. Desmarais recorded with said Registry of Deeds at Book 2279, Page 435.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 2,400 square feet, more or less

Interest: Easement

Date: February 3, 1994

TRACT 105-13

A certain parcel of land with buildings, structures and fixtures thereon, commonly known as the Pawtucket Gate House, located in Lowell, Middlesex County, Massachusetts over the Northern Canal, so called, and the Merrimack River and near School Street and further bounded and described as follows:

Beginning at the most southeasterly corner of the Pawtucket Gate House, said point being 15.35 feet northwesterly from the westerly line of Parcel 29 as shown on the plan hereinafter described; thence

N 46° 55' 36" W, along the most southerly face of the building a distance of 118.70 feet to a point; thence on a curve to the right

NORTHWESTERLY, more or less, along the face of said building a distance of 5 feet to a point; thence

N 43° 12' 10" E, along the most westerly face of said building a distance of 16.40 feet to a building corner, said corner being set back from the southerly line of School Street a distance of 0.60 feet; thence

S 46° 55' 36" E, along the most northerly face of said building a distance of 122.04 feet to the most northeasterly building corner, said corner being set back from the southerly line of School Street a distance of 0.46 feet; thence

S 43° 12' 10" W, along the most easterly face of said building a distance of 19.75 feet to the point of beginning.

Containing 2,400 square feet of land, more or less.

Being shown as a brick gate house on sheet 20 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 24 May 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Meaning and intending the description of the above-referenced parcel to be the same parcel described at Book 3830, Page 169 of the above referenced taking and which description in the taking incorrectly referred to School Street as Pawtucket Street.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 3710 square feet, more or less

Interest: Easement

Date: August 19, 1994

TRACT 105-14

The land and buildings commonly known as the Pawtucket Gatehouse Wall and Lock Chamber, located on the Northern Canal, in Lowell, Middlesex County, Massachusetts, and further bounded and described as follows:

Beginning at a point at the most southeasterly corner of a brick building called the Pawtucket Gatehouse, said point being 15.35 feet distant from the northwesterly line of Parcel 29 as shown on the Plan hereinafter described; thence

N 46° 55' 36" W, along the most southerly face of the building, a distance of 118.70 feet to a point; thence along a curve to the right along the face of said building a distance of 5 feet to a point; thence

N 43° 12' 10" E, along the most westerly face of said building a distance of 16 feet, more or less, to the end of a granite wall at the face of a concrete and granite wall; thence

NORTHWESTERLY, along said concrete and granite wall a distance of 16 feet, more or less; thence

SOUTHERLY, more or less, by the face of a granite wall by the following distances: 10 feet, more or less, thence 13 feet, more or less, and 8 feet, more or less, around a curved section of wall; thence

SOUTHEASTERLY, along the face of the aforementioned granite wall, said face of wall being approximately parallel with and 2.7 feet south of the southerly face of the Pawtucket Gatehouse a distance of 112 feet, more or less, to an angle point; thence along the face of said wall a distance of 10 feet, more or less; thence along the face of said wall a distance of 10 feet more or less; thence along the face of said wall around a curve a distance of 7 feet, more or less; thence along the face of said wall a distance of 10 feet more or less; thence

SOUTHEASTERLY, along a concrete wall, said wall being approximately parallel with School Street a distance of 15 feet, more or less, to a point; thence

N 42° 50' 42" E, along land now or formerly of the Proprietors of Locks and Canals, a distance of 23 feet, more or less, to a drill hole set at the southerly line of School Street; thence

N 46° 51' 34" W, along the southerly line of School Street and land now or formerly of the Proprietors of Locks and Canals a distance of 3 feet, more or less, to a point; thence

NORTHEASTERLY, approximately perpendicular to the southerly line of School Street and under the School Street Bridge along the easterly face of the easterly granite wall of the lock chamber, 58 feet, more or less, to the northerly line of School Street; thence

SOUTHEASTERLY, along said granite wall and the northerly line of School Street a distance of 6 feet, more or less, to a point; thence

NORTHEASTERLY, along the westerly face of a granite wall by land now or formerly of the Proprietors of Locks and canals 120 feet, more or less, and 17 feet, more or less, to the shoreline; thence

SOUTHWESTERLY, along the westerly face of the easterly granite wall of the Northern Canal a distance of 93 feet, more or less, to a point; thence

NORTHWESTERLY, crossing the Lock Chamber a distance of 19 feet, more or less, to the westerly face of the westerly granite of the Lock Chamber; thence

SOUTHWESTERLY, along said face of wall a distance of 36 feet, more or less, to the northerly line of School Street; thence

S 46° 51' 34" E, along the northerly line of School Street a distance of 3 feet, more or less, to a point; thence

SOUTHWESTERLY, approximately perpendicular to the northerly line of School Street and under the School Street Bridge along the westerly face of the westerly granite wall of the lock chamber, 58 feet, more or less, to the southerly line of School Street; thence along the easterly face of the Pawtucket Gatehouse

S 43° 12' 10" W, a distance of 20 feet, more or less, to the point of beginning.

Containing 3710 square feet, more or less.

Being shown on sheet 20 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 3710 square feet, more or less

Interest: Easement

Date: August 19, 1994

TRACT 105-15

The land and buildings commonly known as the Blacksmith Shop, located along the Northern Canal and Merrimack River, in Lowell, Middlesex County, Massachusetts, and further bounded and described as follows:

Beginning at the most southerly corner of the Blacksmith Shop, said corner bearing N 49° 46' 36" W, and being 26.24 feet distant from the northwesterly line of land now or formerly of Flago Realty Corporation; thence along the face of the Blacksmith Shop as follows:

N 66° 55' 23" W, a distance of 8.15 feet to a corner,

N 23° 51' 49" E, a distance of 7.18 feet to a corner,

N 65° 45' 09" W, a distance of 17.26 feet to a corner,

N 24° 09' 04" E, a distance of 45.47 feet to a corner,

S 65° 45' 09" E, a distance of 25.19 feet to a corner, and

S 23° 51' 49" W, a distance of 52.48 feet to the point of beginning.

Containing 1,204 square feet of land, more or less.

Being shown on sheet 20 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 282 square feet, more or less

Interest: Easement

Date: January 13, 1994

TRACT 107-07

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Western Canal, so called and known and numbered as 251 Moody Street, and further bounded and described as follows:

Beginning at an iron pin set on the northeasterly line of Moody Street, said pin being at the southwesterly corner of land now or formerly of Lowell Apartments; thence along said northeasterly line of Moody Street

N 56° 50' 00" W, a distance of 10.28 feet to a point at the back edge of the southeasterly granite wall of the Western Canal; thence along said canal wall:

N 33° 40' 12" E, a distance of 4.62 feet to an iron pin set and

N 45° 45' 12" E, a distance of 47.00 feet to a point at land now or formerly of Lowell Apartments; thence along the northwesterly line of said Lowell Apartments

S 33 ° 09' 51" W, a distance of 50.49 feet to the point of beginning.

Containing 282 square feet of land, more or less.

Being shown as Parcel CB-D, Lot J on sheet 26 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 0.01 of an acre, more or less

Interest: Easement

Date: June 25, 1992
Revised: February 3, 1994

TRACT 107-13

Two certain parcels of land with buildings, structures and fixtures thereon, commonly known as the Rolling Dam Gate House, located in Lowell, Middlesex County, Massachusetts over the Merrimack Canal and Wasteway, so called, and near French Street and further bounded and described as follows:

PARCEL I:

Beginning at the northwesterly corner of the Rolling Dam Gate House, said corner being a point in the southeasterly line of land, now or formerly of Lowell Union Properties Inc., said southeasterly line of land also being the northwesterly line of the Merrimack Canal Wasteway, the aforesaid point of beginning bearing N 48° 15' 38" E, and being 57.58 feet distant from a drill hole found in an angle in the wall of the Merrimack Canal; thence along the southeasterly line of land now or formerly of Lowell Union Properties Inc.

N 48° 15' 38" E by the northwesterly line of the Merrimack Canal Wasteway and the Rolling Dam along the northwesterly face of the Rolling Dam along the northwesterly face of the rolling Dam Gate House, a distance of 11.15 feet the a point;

Thence, crossing the Rolling Dam and running along the northeasterly face of the Rolling Dam Gate house S 42° 02' 28" E, a distance of 17.90 feet to a point on the northwesterly line of land now or formerly of Boott Mills, being the southeasterly line of the Merrimack Canal Wasteway;

Thence, running through the Rolling Dam Gate House along said southeasterly line of the Merrimack Canal Wasteway

S 48° 17' 38" W, a distance of 27.29 feet to a point on the southwesterly building face of the Rolling Dam Gate House, said point bearing N 20° 06'35" E and being 0.45 feet distant from the most southwesterly corner thereof; thence crossing the Merrimack Canal Wasteway and running along the westerly and southwest building lines of the Rolling Dam Gate House by two courses as follows:

N 20° 06' 35" E, a distance of 18.26 feet to a point, and

N 42° 02' 28" W, a distance of 9.26 feet to the point of beginning.

Containing 269 square feet of land, which is 0.01 of an acre, more or less.

PARCEL II:

Beginning at a point on the northeasterly face of the Rolling Dam Gate House, said point being on the southeasterly line of the Merrimack Canal Wasteway and bearing S 48° 17' 38" W, and being 19.37 feet distant from an iron pin set at the northwesterly corner of Parcel CB-L/5721 as shown on the plan hereinafter described; thence running the following four courses by land now or formerly of Boott Mills along the building face of the Rolling Dam Gate House:

S 42° 02' 28" E, a distance of 4.07 feet to a point,

S 20° 06' 35" W, a distance of 22.94 feet to a point, said point bearing N 42° 45' 53" W, and being 34.96 feet distant from the most northerly corner of Store House No. 1,

N 68° 42' 56" W, a distance of 16.49 feet to a point and

N 20° 06' 35" E, a distance of 0.45 feet to a point on the southeasterly line of the Merrimack Canal Wasteway;

Thence, along said southeasterly line of the Merrimack Canal Wasteway N 48° 17' 38" E, a distance of 27.29 feet to the point of beginning.

Containing 248 square feet of land, more or less, which is 0.01 of an acre, more or less.

Both Parcels I and II being shown as the Rolling Dam Gate House North and South on sheet 19 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 24 May 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 805 square feet, more or less

Interest: Easement

Date: January 13, 1994

TRACT 107-15

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Western Canal, so called and known and numbered as 271 Moody Street, and further bounded and described as follows:

Beginning at a point on the northeasterly line of Moody Street, said point being an iron pin set at the southeasterly corner of land now or formerly of the Lowell Apartments; thence along the southeasterly line of said Lowell Apartments

N 33 ° 10' 15" E, a distance of 212.43 feet to a point on the southwesterly line of French Street Extension; thence along said line of French Street Extension

S 56° 01' 24" E, a distance of 1.63 feet to a point at the back edge of the northwesterly granite wall of the Western Canal; thence along the back edge of said canal wall as follows:

S 33° 09' 14" W, a distance of 4.16 feet to an iron pin set,

S 33° 09' 14" W, a distance of 151.42 feet to an iron pin set,

S 17° 32' 06" W, a distance of 57.31 feet to an iron pin set and

S 28° 57' 00" W, a distance of 1.65 feet to a point on the northeasterly line of Moody Street; thence along said line of Moody Street

N 56° 50' 00" W, a distance of 17.25 feet to the point of beginning.

Containing 805 square feet of land, more or less.

Being shown as Parcel CB-C, Lot I on sheet 26 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 2,511 square feet, more or less

Interest: Easement

Date: February 1, 1994
Revised: March 27, 1995

TRACT 107-21

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Eastern Canal and Merrimack Wasteway, so called, and further bounded and described as follows:

Beginning at a point at the southeasterly corner of the parcel, said point being on the northeasterly line of land now or formerly of Boott Mills, and bearing N 41° 34' 09" W, and being 60.23 feet distant from the westerly termination of Amory Street; thence

N 41° 34' 09" W, along the northeasterly line of land now or formerly of Boott Mills, a distance of 158.92 feet to an iron pin set at the southeasterly face of the southeasterly wall of the Rolling Dam; thence

N 48° 17' 38" E, along said southeasterly face of the southeasterly wall of the Rolling Dam, a distance of 8.61 feet to an iron pin set at an angle in the southerly wall of the Merrimack Wasteway; thence

N 70° 36' 40" E, along the southerly face of a wall, a distance of 9.91 feet to a cross-cut set at an angle in said wall; thence

S 40° 30' 36" E, along the southwesterly face of the southwesterly wall of the Eastern Canal, a distance of 4.65 feet to a point on the northwesterly face of a brick building; thence running along the face of said brick building by five courses as follows:

S 48° 17' 38" W, a distance of 0.71 feet to a point,

S 40° 24' 35" E, a distance of 10.40 feet to a point,

S 50° 12' 21" W, a distance of 12.73 feet to a point,

S 40° 24' 35" E, a distance of 21.36 feet to a point, and

N 48° 23' 37" E, a distance of 13.50 feet to a point at the southwesterly face of the southwesterly wall of the Eastern Canal; thence running along said southwesterly face of the southwesterly wall of the Eastern Canal

S 43° 08' 52" E, a distance of 35.00 feet to a point at the most westerly corner of the Boott Dam Gate House as shown on the plan hereinafter described; thence

S 38° 32' 55" E, along the southwesterly face of the Boott Dam Gate House a distance of 11.07 feet to a point at the most southerly corner thereof; thence along the southwesterly face of the southwesterly wall of the Eastern Canal

S 42° 29' 19" E, a distance of 72.12 feet to a point; thence

S 45° 11' 23" W, along the northwesterly edge of a concrete capstone, a distance of 18.69 feet to a PK nail set at the point of beginning.

Containing 2,511 square feet of land, more or less.

Being shown as Parcel CB-L/5721 on sheet 19 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 4,938 square feet, more or less

Interest: Easement

Date: January 13, 1994

TRACT 107-22

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Western Canal, so called and Suffolk Street, and between French Street Extension and Hall Street and further bounded and described as follows:

Beginning at a point on the southeasterly line of Suffolk Street, said point being at a thirty foot right-of-way; thence along said thirty foot right-of way

S 41° 36' 20" E, a distance of 10.40 feet to a PK nail set in a wood deck; thence along the back edge of the northwesterly granite wall of the Tremont Wasteway

S 48° 19' 26" W, a distance of 475.86 feet to a PK nail set in a wall; thence along said wall

N 40° 26' 22" W, a distance of 10.36 feet to a point on the southeasterly line of Suffolk Street; thence along said line of Suffolk Street

N 48° 19' 10" E, a distance of 475.65 feet to the point of beginning

Containing 4,938 square feet of land, more or less.

Being shown as Parcel CB-E, Lot A on sheet 25 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 10,905 square feet, more or less

Interest: Easement

Date: January 13, 1994

TRACT 107-23

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Western Canal, so called, known and numbered as 540 Market Street and further bounded and described as follows:

Beginning at a drill hole set at the northeasterly corner of Suffolk Street and Jefferson Street; thence running along the easterly line of Suffolk Street

N 11° 11' 30" W, a distance of 482.44 feet to a spike set in the granite curb at the point of curvature leading to Market Street; thence

Northeasterly, more or less, by a curve to the right having a radius of 11.46 feet, an arc length of 26.87 feet to an x-cut set in the concrete walk; thence running along the southerly line of Market Street

S 56° 46' 50" E, a distance of about 18 feet to the westerly shoreline of the Western Canal; thence along the westerly shoreline of said Western Canal

Southerly, more or less, a distance of about 480 feet to a point on the northerly line of Jefferson Street; thence running along said northerly line of Jefferson Street

S 78 52' 10" W, a distance of about 25 feet to the point of beginning.

Containing 10,905 square feet of land, more or less.

Being shown as Parcel CB-C, Lot C on sheets 27 and 28 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 8,635 square feet, more or less

Interest: Easement

Date: January 13, 1994

TRACT 107-24

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Western Canal, so called, known and numbered as 520 Market Street and further bounded and described as follows:

Beginning at a spike set at the northwesterly corner of Jefferson Street and Lewis Street; thence running along the northerly line of Jefferson Street,

S 78° 52' 10" W, a distance of about 23 feet to the easterly shoreline of the Western Canal; thence along said shoreline of the Western Canal

Northerly, more or less, a distance of about 452 feet to a point on the southwesterly line of Market Street; thence along said southwesterly line of Market Street

S 56° 46' 50" E, a distance of about 45 feet to a drill hole set in the concrete sidewalk at the southwesterly corner of Market Street and Lewis Street; thence along the westerly line of Lewis Street

S 11° 11' 30" E, a distance of 411.18 feet to the point of beginning

Containing 8,635 square feet of land, more or less.

Being shown as Parcel CB-D, Lot D on sheets 27 and 28 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: City of Lowell and Comm. of MA/DEM
Date of Description: March 16, 1994
Revised: Oct. 7, 1994
Interest: Easement

Tract 107-25(Ecumenical Plaza)

All of that certain brick and concrete platform, together with the air rights, lying over the Western Canal in the City of Lowell, County of Middlesex and Commonwealth of Massachusetts, excluding the canal walls, and known as Ecumenical Plaza; Said Plaza is shown on Sheet No. 28 of a plan entitled "Lowell Canal System, Commonwealth of Massachusetts, Department of Environmental Management, Division of Forests and Parks, Lowell Heritage State Park, Lowell Massachusetts," and prepared by Atlantic Engineering and Survey Consultants and recorded in the Middlesex North Registry of Deeds in Plan Book 157, Plan 69.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 3,115 square feet, more or less

Interest: Easement

Interest: Easement

Date: February 3, 1994

TRACT 108-21

A certain parcel of land with buildings, structures and fixtures thereon, commonly known as the Massachusetts Wasteway Gate House, located in Lowell, Middlesex County, Massachusetts over the Eastern Canal, so called, and near Bridge Street and further bounded and described as follows:

Beginning at the northwesterly corner of the Massachusetts Wasteway Gate House, said corner bearing S 41° 44' 51" E, and being 3.74 feet distant from the southeasterly line of Bridge Street; thence running along the face of the Massachusetts Wasteway Gate House by land now or formerly of the Proprietors of Locks and Canals, by three courses as follows:

N 48° 15' 09" E, a distance of 7.67 feet to a corner,

S 41° 44' 51" E, a distance of 26 feet to a corner, and

S 48° 15' 09" W, a distance of 7.67 feet to the most southerly corner of said Gate House, being a point on the southeasterly side of the Eastern Canal; thence along the southwesterly face of the Massachusetts Wasteway Gate House

N 41° 44' 51" W, a distance of 26 feet to the point of beginning.

Containing 199 square feet of land, more or less.

Being shown as the Massachusetts Wasteway Gate House on sheet 18 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 24 May 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 16,319 square feet, more or less

Interest: Easement

Date: February 1, 1994

TRACT 110-02

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Pawtucket Canal so called, and known and numbered as 722 Broadway and further bounded and described as follows:

Beginning at an iron pin set at the northwesterly corner of the parcel; said pin being a point on the southerly line of Broadway; said point bearing N 82° 56' 05" E and being 16.85 feet distant from an angle in said line; thence along said southerly line of Broadway

N 82° 56' 05" E, a distance of 31.29 feet to a point at the back edge of the concrete wall of the Pawtucket Canal; thence running along the back edge of said wall as follows:

S 18° 33' 43" E, a distance of 103.20 feet to an iron pin set at an angle in the wall,

S 08° 06' 33" W, a distance of 65.99 feet to an iron pin set at an angle in the wall, and

S 05° 50' 20"E, a distance of 192.18 feet to an iron pin set at an angle in the wall; thence continuing along the back edge of the concrete and then granite wall of the Pawtucket canal as follows:

S 15° 12' 18" E, a distance of 231.72 feet to an x-cut set at an angle in the wall, and

S 31° 44' 31" E, a distance of 17.94 feet to a point on the northerly line of location of the Boston and Maine Railroad; thence running along said railroad location line as follows:

N 84° 50' 16" W, a distance of 14.34 feet to a drill hole set at an angle in said location line, and

S 82° 00' 51" W, a distance of 16.74 feet to an iron pin set at the easterly line of land now or formerly of the City of Lowell; thence running along said land of the City of Lowell

N 15° 14' 25" W, a distance of 264.45 feet to an iron pin found at the southerly corner of land now or formerly of the Commonwealth of Massachusetts; thence running along said land of the Commonwealth of Massachusetts by three courses as follows:

N 05° 40' 50" W, a distance of 178.07 feet to an iron pin found,

N 08° 20' 10" E, a distance of 72.30 feet to an iron pin set, and

N 18° 27' 01" E, a distance of 91.21 feet to the point of beginning.

Containing 16,319 square feet of land, more or less.

Being shown as Parcel 7A on sheet 5 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3630, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 57,348 square feet, more or less

Interest: Easement

Date: February 1, 1994

TRACT 110-03

Two certain parcels of land located in Lowell, Middlesex County, Massachusetts along the Pawtucket Canal so called, and known and numbered as 713 Broadway and further bounded and described as follows:

PARCEL I:

Beginning at a stone bound found at the southwesterly corner of the parcel, said point being located at an angle on the northerly line of Broadway; thence

N 21° 35' 30" W, by land now or formerly of the Commonwealth of Massachusetts, 190.48 feet to a concrete bound found; thence

N 21° 35' 30" W, by land now or formerly of Endevor Incorporated 269.52 feet to a point; thence by land now or formerly of the Proprietors of Locks and Canals by five courses as follows:

S 40° 51' 32" E, a distance of 63.10 feet to a point,

S 30° 21' 02" E, a distance of 98.70 feet to a point,

S 28° 42' 32" E, a distance of 180.03 feet to a point,

S 27° 06' 12" E, a distance of 88.85 feet to a point, and

S 03° 54' 52" E, a distance of 51.47 feet to a point on the northerly line of Broadway; thence

S 82° 56' 05" W, by said northerly line of Broadway 52.74 feet to the point of beginning.

Containing 19,848 square feet of land, more or less.

Being shown as Parcel 8A, Lot 1 on sheet 4 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 24 May 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

PARCEL II:

Beginning at a point at the southwesterly corner of the parcel on the northerly line of Broadway, said point being N 82° 56' 05" E, a distance of 52.74 feet of a stone bound found on the northerly line of Broadway; thence by land now or formerly of the Proprietors of Locks and Canals by five courses as follows:

N 03° 54' 52" W, a distance of 51.47 feet to a point,

N 27° 06' 12" W, a distance of 88.85 feet to a point,

N 28° 42' 32" W, a distance of180.03 feet to a point,

N 30° 21' 02" W, a distance of 98.70 feet to a point, and

N 40° 51' 32" W, a distance of 63.10 feet to a point, thence by land now or formerly of the Commonwealth of Massachusetts by four courses as follows:

N 39° 26' 01" W, a distance of 11.26 feet to a point,

N 41° 26' 13" W, a distance of 65.21 feet to a point,

N 40° 55' 22" W, a distance of 28.28 feet to a point, and

N 38° 57' 44" W, a distance of 6.35 feet to a point; thence continuing by land now or formerly of the Commonwealth of Massachusetts by 19 courses as follows:

N 40° 51' 40" W, a distance of 59.18 feet to a point,

N 37° 55' 55" W, a distance of 31.65 feet to a point,

N 29° 43' 39" W, a distance of 47.04 feet to a point,

N 25° 59' 51" W, a distance of 18.34 feet to a point,

N 26° 07' 46" W, a distance of 147.13 feet to a point,

N 57° 28' 20" W, a distance of 0.73 feet to a point,

N 22° 42' 54" W, a distance of 48.48 feet to a point,

N 21° 32' 50" W, a distance of 20.27 feet to a point,

N 14° 11' 07" W, a distance of 141 feet to a point,

N 04° 08' 34" E, a distance of 60.21 feet to a point,

N 10° 37' 49" W, a distance of 66.11 feet to a point,

N 10° 13' 54" W, a distance of 42.29 feet to a point,

N 19° 09' 50" W, a distance of 17.85 feet to a point,

N 19° 17' 12" W, a distance of 59.17 feet to a point,

N 24° 17' 55" W, a distance of 43.27 feet to a point,

N 29° 51' 29" W, a distance of 45.82 feet to a point,

N 33° 34' 42" W, a distance of 36.78 feet to a point,

N 40° 05' 46" W, a distance of 80.63 feet to a point, and

N 40° 40' 59" W, a distance of 58.49 feet to a drill hole with lead plug and brass pin found at the intersection with the southerly line of Pawtucket Street; thence

N 50° 30' 01" E, along the southerly line of Pawtucket Street, a distance of 6 feet, more or less, to the westerly face of a granite wall on the westerly side of the Pawtucket Canal; thence

SOUTHERLY, more or less, along the westerly face of the aforementioned wall, a distance of 45 feet, more or less, to the end of the wall; thence continuing

SOUTHERLY, more or less, along the westerly bank of the Pawtucket Canal a distance of 1,281 feet to a granite wall; thence continuing

SOUTHERLY, more or less, along the westerly face of said granite wall a distance of 81 feet, more or less, to a drill hole set along the westerly face of the granite wall at the top of a set of concrete steps; thence

S 27° 16' 45" E, along the westerly face of the aforementioned granite wall, a distance of 40.79 feet to the northerly face of a building known as the Locking Gate House; thence

S 62° 43' 24" W, along the northerly face of the aforementioned building a distance of 7.80 feet to a building corner; thence

S 27° 16' 45" E, along the westerly face of the aforementioned building a distance of 16.06 feet to a building corner; thence

N 62° 43' 24" E, along the southerly face of the aforementioned building a distance of 6 feet, more or less, to the westerly face of a granite wall on the westerly side of the Pawtucket Canal; thence

SOUTHERLY, more or less, along the aforementioned wall a distance of 55 feet more or less to the northwesterly corner of a building known as the Francis Gate House; thence

S 27° 26' 58" E, along the westerly face of the Francis Gate House a distance of 13.41 feet to the southwesterly corner of the Francis Gate House; thence by the westerly face of a granite wall on the westerly side of the Pawtucket Canal by five courses as follows:

SOUTHERLY, 12 feet, more or less,

WESTERLY, 13 feet, more or less,

SOUTHERLY, 3 feet, more or less,

EASTERLY, 16 feet, more or less, and

SOUTHERLY, 6.4 feet, more or less, to an iron pin set at the westerly face of said wall; thence continuing

SOUTHERLY, more or less, along the westerly face of the aforementioned wall 51 feet, more or less, to an angle point in the wall; thence continuing

SOUTHERLY, more or less, along said wall a distance of 25 feet, more or less, to an iron pin set at the westerly face of said wall, said iron pin being 75.37 feet on a bearing of S 21° 00' 01" E, from the last mentioned iron pin; thence

SOUTHWESTERLY, more or less, along the westerly face of the aforementioned granite wall a distance of 28 feet, more or less to the northerly line of Broadway; thence

S 82° 56' 05" W, along Broadway a distance of 22 feet, more or less, to the point of beginning.

Containing 37,500 square feet of land, more or less.

Being shown as Parcel 8B on sheets 2, 3 and 4 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 24 May 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 0.9 of an acre, more or less

Interest: Easement

Date: February 1, 1994

TRACT 110-06

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Pawtucket Canal so called, and known and numbered as 380 School Street and 577.2 Middlesex Place and further bounded and described as follows:

Beginning at a point on the easterly line of School Street, said point being the northeasterly corner of Parcel CB-A/4 as shown on sheet 8 of the plan hereinafter described; thence

S 64° 34' 09" E, a distance of 2.24 feet to an x-cut set at the back edge of the southerly granite wall of the Pawtucket Canal; thence running along the back edge of said canal wall as follows:

S 59° 30' 00" E, a distance of 105.94 feet to an x-cut set,

S 63° 37' 19" E, a distance of 193.60 feet to an x-cut set,

S 73° 36' 36" E, a distance of 97.13 feet to an x-cut set,

S 73° 37' 46" E, a distance 731.97 feet to an x-cut set,

EASTERLY, more or less, by a curve to the left of a distance of 177 feet, more or less, to a drill hole set,

EASTERLY, more or less, still by said curve, a distance of 299 feet, more or less to an iron pin set,

NORTHEASTERLY, more or less, by a curve to the left, a distance of 148 feet, more or less, to an x-cut set, and

N 57° 32' 42" E, a distance 249.31 feet to a point at the northwesterly corner of Parcel 2B/2C-1/2C-2 as shown on sheet 9 of said plan; thence along the southeasterly line of Parcel 2B/2C-1/2C-2 and land now or formerly of Thomas M. Hughes

S 22° 45' 06" E, a distance of 108.06 feet to a point at an angle in the northerly line of Middlesex Place

S 68° 00' 59" W, a distance of 25 feet to a point at the southeasterly corner of land now or formerly of John A. and Sandra L. Crowe; thence along the easterly line of Crowe

N 22° 45' 06" W, a distance of 85.36 feet to a point; thence along the northerly line of Crowe

S 57° 20' 02" W, a distance of 277.58 feet to a point at land now or formerly of Philip J. Stratos; thence along the northerly line of said Stratos

S 60° 05' 29" W, a distance of 104.53 feet to a point of curvature; thence along the northerly line of land now or formerly of said Stratos, Peter D. Hallissy and Lowell Boys Club Association

SOUTHWESTERLY, more or less, by a curve to the right having a radius of 616 feet, an arc length of 501.72 feet to a point at the northwesterly corner of land now or formerly of said Lowell Boys Club Association; thence along the westerly line of the Lowell Boys Club Association

S 16° 16' 54" E, a distance of 5 feet to a point at land now or formerly of Josephine M. Brady; thence along the northerly line of Brady as follows:

N 71° 50' 47" W, a distance of 52.05 feet to a point,

N 71° 59' 55" W, a distance of 168.82 feet to a point, and

N 73° 44' 25" W, a distance of 289.62 feet to a point at land now or formerly of Donald A. Delmore; thence by the northerly line of said Delmore and of land now or formerly of Ronald E. and Denise E. Belley, as follows:

N 73° 44' 25" W, a distance of 291.65 feet to a point,

N 63° 41' 05" W, a distance of 198.65 feet to a point, and

N 59° 37' 45" W, a distance of 93.37 feet to a point on the easterly line of School Street; thence along said easterly line of School Street

N 09° 18' 05" W, a distance of 23.58 feet to the point of beginning.

Containing 39,000 square feet of land, more or less, which is 0.9 of an acre, more or less.

Being shown as Parcel CB-A/5 on sheets 8 and 9 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 5 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 0.52 of an acre, more or less

Date: February 1, 1994

TRACT 110-07

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Pawtucket Canal so called, and known and numbered as 379 School Street and further bounded and described as follows:

Beginning at the northwesterly corner of the parcel, said corner being a point on the southerly line of location of the Boston and Maine Railroad, and being at the northeasterly corner of Parcel CB-A/2 as shown on the plan hereinafter described; thence along the southerly location line of said railroad

N 86° 50' 03" E, a distance of 71.11 feet to a point at the back edge of the southerly granite wall of the Pawtucket Canal; thence running along the back edge of said canal wall as follows:

S 43° 21' 58" E, a distance of 64.39 feet to an iron pin set,

S 56° 00' 37" E, a distance of 45.26 feet to an x-cut set,

S 59° 03' 48" E, a distance of 95.68 feet to a point,

S 58° 56' 41" E, a distance of 86.22 feet to a drill hole set,

WESTERLY, more or less, by a curve to the left a distance of 207 feet, more or less, to a drill hole set,

S 84° 07' 29" E, a distance of 133.92 feet to a drill hole set,

S 88° 59' 18" E, a distance of 29.40 feet to a drill hole set,

S 89° 44' 14" E, a distance of 42.79 feet to a drill hole set,

N 87° 29' 24" E, a distance of 39.60 feet to a drill hole set,

N 83° 30' 57" E, a distance of 103.57 feet to an x-cut set,

N 83° 29' 15" E, a distance of 62.46 feet to an x-cut set, and

S 85° 49' 54" E, a distance of 118.37 feet to an x-cut set, and

SOUTHEASTERLY, more or less, by a curve to the right a distance of 59 feet, more or less, to an x-cut set; thence

S 64° 34' 09" E, a distance of 6.16 feet to a point on the westerly line of School Street; thence along said westerly line of School Street

S 09° 18' 05" E, a distance of 22.36 feet to a point at land now or formerly of Marinel Transportation Inc.; thence along the northerly line of land of Marinel Transportation, Inc. and land of Nicholas C. Sarris et. al. as follows:

N 73° 27' 35" W, a distance of 93.55 feet to a point,

N 85° 19' 55" W, a distance of 68 feet to a point of curvature,

WESTERLY, more or less, by a curve to the right having a radius of 122 feet, an arc length of 25.20 feet to a point,

S 83° 30' 25" W, a distance of 160 feet to a point of curvature,

WESTERLY, more or less, by a curve to the right having a radius of 447 feet, an arc length of 52.03 feet to a point,

N 89° 48' 15" W, a distance of 50 feet to a point of curvature,

WESTERLY, more or less, by a curve to the right having a radius of 626 feet, an arc length of 76.05 feet to a point,

N 83° 13' 35" W, a distance of 80 feet to a point of curvature, and

NORTHWESTERLY, more or less, by a curve to the right having a radius of 550.22 feet, an arc length of 187.46 feet to a point at the end of a twenty foot wide private way; thence crossing the end of said private way

N 64° 26' 11" W, a distance of 28.22 feet to the southeasterly corner of land now or formerly of P.H. Macheras Oil Company; thence along the northeasterly line of land of said P.H. Macheras Oil Company by two courses as follows:

N 58° 56' 27" W, a distance of 292.59 feet to a point, and

N 71° 55' 57" W, a distance of 45.70 feet to a point at the southeasterly corner of Parcel CB-A/2 as shown on the plan herinafter described; thence along the easterly line of land of said Parcel CB-A/2

N 03° 30' 25" W, a distance of 12.54 feet to the point of beginning.

Containing 22,500 square feet of land, more or less, which is 0.52 of an acre, more or less.

Being shown as Parcel CB-A/3 on sheet 7 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 5 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

TRACT 110-20

The following six parcels of land, together with the buildings thereon, located on the Pawtucket Canal, in Lowell, Middlesex County, Massachusetts between Pawtucket Street and Broadway Street and further bounded and described as follows:

PARCEL I:

Beginning at an iron pin set at the most northerly corner of the parcel, said pin being set at the back edge of the granite wall of the Pawtucket Canal, thence running along the exposed back edge of said wall

S 70° 45' 09" E, a distance of 51.24 feet to an iron pin set; thence continuing along the exposed back edge of said wall by three courses as follows:

SOUTHEASTERLY, more or less, a distance of about 37 feet to a chisel-cut set in the wall, said chisel-cut bearing S 45° 23' 13" E, and being 34.88 feet distant from the last point described,

SOUTHWESTERLY, more or less, a distance of about 3 feet, and

SOUTHERLY, more or less, a distance of about 4 feet to the most westerly corner of the Hydraulic Gatehouse, said corner bearing S 07° 38' 47" W, and being 5.59 feet distant from the last mentioned chisel-cut; thence along the southwesterly face of the Hydraulic Gatehouse

S 20° 48' 37" E, a distance of 19.39 feet to the most southerly corner of said Gatehouse; thence running along the southerly face of the Hydraulic Gatehouse

N 69° 11' 23" E, a distance of 4 feet, more or less, to a point; thence running perpendicular to the last mentioned course

SOUTHERLY, more or less, a distance of about 13 feet to a point on the westerly edge of a stone wall; thence running along the edge of said wall as follows:

SOUTHWESTERLY, more or less, a distance of about 22 feet to a point,

SOUTHEASTERLY, more or less, a distance of about 3 feet to a point,

NORTHEASTERLY, more or less, a distance of about 18 feet to a point, and

SOUTHERLY, more or less, a distance of about 41 feet to a drill hole set at the back of exposed edge of said wall, said drill hole bearing S 13° 10' 24" E, and being 58.36 feet distant from the aforementioned southwesterly corner of the Hydraulic Gatehouse; thence continuing along the back edge of the exposed wall as follows:

S 19° 32' 24" W, a distance of 23.95 feet to an iron pin set,

S 88° 10' 35" W, a distance of 11.14 feet to an iron pin set,

N 29° 55' 13" W, a distance of 13.01 feet to an iron pin set,

N 35° 19' 04" W, a distance of 12.82 feet to an iron pin set, and

N 11° 33' 48" W, a distance of 18.18 feet to a drill hole set; thence continuing along the edge of exposed wall:

NORTHEASTERLY, more or less, a distance of about 14 feet to a point,

NORTHWESTERLY, more or less, a distance of about 3 feet to a point,

SOUTHWESTERLY, more or less, a distance of about 14 feet to a point,

NORTHWESTERLY, more or less, a distance of about 12 feet to the southeasterly corner of the Francis Gatehouse, said corner bearing N 36° 56' 54" W, and being 15.26 feet distant from the last mentioned drill hole; thence running along the northeasterly face of the Francis Gatehouse

N 27° 26' 58" W, a distance of 13.41 feet to the northeasterly corner thereof; thence running along the back of the exposed granite wall

N 17° 56' 25" W, a distance of 9.09 feet to a drill hole set in the bottom step of some granite steps; thence continuing along the back edge of the wall

NORTHWESTERLY, more or less, a distance of about 32 feet to a point on the southerly wall of the Locking Gatehouse; thence running along the face of the north end of the Gatehouse as follows:

N 62° 43' 24" E, a distance of 7 feet to the northeasterly corner of the Gatehouse,

N 27° 16' 45" W, a distance of 16.06 feet to the northerly corner of the Gatehouse,

S 62° 43' 24" W, a distance of about 8.7 feet to a point on the northerly face of the Locking Gatehouse, said point being at the back of the exposed granite wall as hereinbefore mentioned; thence running along the back of said wall

NORTHWESTERLY, more or less, a distance of about 0.7 feet to a drill hole set, said drill hole bearing S 66° 57' 39" W, and being 8.71 feet distant from the aforementioned northerly corner of the Locking Gatehouse; thence continuing along the back edge of said wall

N 22° 50' 38" W, a distance of 32.98 feet to the point of beginning.

Containing 5,660 square feet of land, more or less.

Being shown as Parcel 8-C on sheet 4 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

PARCEL II:

Beginning at an iron pin set at the northwesterly corner of Broadway and Madonna Circle; thence along the northerly line of Broadway

S 82° 56' 05" W, a distance of about 70 feet to a point at the back edge of the easterly granite wall of the Pawtucket Canal; thence along the back edge of said canal wall

NORTHERLY, more or less, a distance of about 163 feet to an angle in said wall; thence along the back edge of a granite wall appurtenant to the Pawtucket Canal as follows:

SOUTHEASTERLY, more or less, a distance of about 26 feet,

NORTHEASTERLY, more or less, a distance of about 3 feet, and

NORTHWESTERLY, and WESTERLY, more or less, a distance of about 94 feet to a point on said wall at Parcel 8-C, as described above; thence along the easterly line of Parcel 8-C

NORTHERLY, more or less, a distance of about 13 feet to the southerly face of the Hydraulic Gatehouse; thence by the face of said gatehouse

N 69° 11' 23" E, a distance of about 67 feet to the southeasterly corner thereof, and

N 20° 48' 37" W, a distance of 19.39 feet to the northeast corner of said gatehouse; thence along the edge of the easterly granite wall of the Pawtucket Canal as follows:

NORTHERLY, more or less, a distance of about 96 feet,

WESTERLY, more or less, a distance of about 3 feet, and

SOUTHERLY, more or less, a distance of about 38 feet to a point on the easterly shoreline of aforesaid Pawtucket Canal; thence along said easterly shoreline

NORTHWESTERLY, more or less, a distance of about 1,464 feet to a point at the back edge of the easterly granite wall of said Pawtucket Canal; thence along said canal wall

NORTHWESTERLY, more or less a distance of about 26 feet to a point on the southerly line of Pawtucket Street; thence along said line of Pawtucket Street

N 50° 30' 01" E. a distance of about 24 feet to an iron pin set at land now or formerly of the City of Lowell; thence along the westerly line of land of said City of Lowell as follows:

S 42° 57' 18" E, a distance of 18.50 feet to an iron pin set,

S 52° 22' 18" E, a distance of 45.33 feet to a drill hole set,

S 51° 03' 18" E, a distance of 26.92 feet to an iron pin set,

S 45° 57' 08" E, a distance of 99.63 feet to an iron pin set,

S 27° 45' 08" E, a distance of 9.13 feet to a point,

S 23° 43' 08" E, a distance of 166.68 feet to a drill hole set,

S 20° 16' 08" E, a distance of 18.32 feet to a drill hole set,

S 06° 36' 38" E, a distance of 108.50 feet to an iron pin set,

S 11° 40' 38" E, a distance of 236.01 feet to an iron pin set,

S 17° 29' 58" E, a distance of 36.11 feet to an iron pin set,

S 22° 11' 38" E, a distance of 36.39 feet to an iron pin set,

S 30° 12' 38" E, a distance of 131.48 feet to a drill hole in a stone bound found,

S 30° 12' 38" E, a distance of 100.00 feet to a drill hole in a stone bound found,

S 30° 12' 37" E, a distance of 53.52 feet to a drill hole in a stone bound found,

SOUTHEASTERLY, more or less, by a curve to the left having a radius of 212.80 feet, an arc length of 39.25 feet to a drill hole in a stone bound found, and

S 40° 46' 41" E, a distance of 60.26 feet to a point at land now or formerly of Thomas Riley; thence along the southwesterly line of Riley as follows:

S 40° 46' 41: E, a distance of 91.60 feet to a drill hole in a stone bound found,

S 51° 27' 21" E, a distance of 93.41 feet to a point, and

S 55° 19' 01" E, a distance of 108.23 feet to a P.K. nail set at Madonna Circle; thence along the westerly line of Madonna circle

S 11° 00' 40" E, a distance of 253.76 feet to the point of beginning.

Meaning and intending to exclude the canal walls of the Pawtucket Canal.

Containing 26,200 square feet of land, more or less.

Being shown as Parcel 13B on sheets 2, 3, and 4 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

PARCEL III:

Beginning at the southeasterly corner of the Hydraulic Gatehouse, said corner being 20.43 feet distant from the westerly line of Madonna Circle; thence along the southerly wall of the gatehouse by Parcel 13B and Parcel 8-C

S 69° 11' 23" W, a distance of 71.00 feet to the southwest corner thereof; thence along the westerly wall of the gatehouse, by Parcel 8-C

N 20° 48' 37" W, a distance of 19.39 feet to the northwest corner thereof; thence along the northerly wall of the gatehouse by Parcel 8-C and crossing the Pawtucket Canal

N 69° 11' 23" E, a distance of 71.00 feet to the northeast corner thereof; thence along the easterly wall of the gatehouse

S 20° 48' 37" E, a distance of 19.39 feet to the point of beginning.

Containing 1,377 square feet of land, more or less.

Being shown as Hydraulic Gatehouse - Guard Locks, on sheet 4 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

PARCEL IV:

Beginning at the most northwesterly corner of the Francis Gatehouse, said corner being 19.34 feet distant from the northeasterly line of Parcel 8-A, Lot 1 and being on the easterly line of Parcel 8B as shown on the Plan hereinafter described; thence

N 62° 17' 23" E, along the northerly face of the Francis Gatehouse and across the lock chamber, a distance of 36.60 feet to the most northerly corner thereof; thence running along the easterly building face

S 27° 26' 58" E, a distance of 13.41 feet to the southeasterly corner of said Francis Gatehouse; thence running along the southerly building face, and again crossing the lock chamber

S 62° 17' 23" W, a distance of 36.60 feet to the southeast building corner; thence running along the westerly building face, being the easterly line of Parcel 8B,

N 27° 26' 58" W, a distance of 13.41 feet to the point of beginning.

Containing 491 square feet of land, more or less.

Being shown as Francis Gatehouse on sheet 4 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

PARCEL V:

Beginning at the most southwesterly corner of the Locking Gatehouse, said point being 12.64 feet distant from the easterly line of Parcel 8A, Lot 1, as shown on the Plan hereinafter described, and being on the easterly line of Parcel 8B; thence

N 27° 16' 45" W, along Parcel 8B, a distance of 16.06 feet to a building corner; thence

N 62° 43' 24" E, along the northerly face of the building, crossing over the lock chamber and by part of Parcel 8-C to the most northeasterly building corner a distance of 51.29 feet; thence

S 27° 16' 45" E, along the most easterly face of said building a distance of 16.06 feet to a corner; thence

S 62° 43' 24" W, along the face of said building a distance of 7.89 feet to a corner; thence

S 27° 16' 45" E, along the face of said building a distance of 8.00 feet to the most southeasterly corner of said building; thence

S 62° 43' 24" W, along the most southerly face of said building a distance of 35.40 feet to a corner; thence

N 27° 16' 45" W, along the face of said building a distance of 8.00 feet to a corner; thence

S 62° 43' 24" W, along the face of said building a distance of 8.00 feet to the point of beginning.

Containing 1,000 square feet of land, more or less.

Being shown as Locking Gatehouse on sheet 4 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

PARCEL VI:

Beginning at a drill hole set at the northwesterly corner of the parcel along the westerly face of the westerly granite lock chamber wall at the top of a set of granite steps; thence

S 27° 16' 45" E, along the westerly face of the aforementioned granite wall, a distance of 40.79 feet to the northerly face of a building known as the Locking Gatehouse; thence

S 62° 43' 24" W, along the northerly face of the aforementioned building a distance of 7.80 feet to a building corner; thence

S 27° 16' 45" E, along the westerly face of the aforementioned building a distance of 16.06 feet to a building corner; thence

N 62° 43' 24" E, along the southerly face of the aforementioned building a distance of about 6 feet to the westerly face of a granite wall on the westerly side of the Pawtucket Canal; thence

SOUTHERLY, more or less, along the aforementioned wall a distance of about 55 feet to the northwesterly corner of a building known as Francis Gatehouse; thence

S 27° 26' 58" E, along the westerly face of the Francis Gatehouse a distance of 13.41 feet to the southwesterly corner of the Francis Gatehouse; thence by the westerly face of a granite wall on the westerly side of the Pawtucket Canal by 5 courses as follows:

SOUTHERLY, about 12 feet,

WESTERLY, about 13 feet,

SOUTHERLY, about 3 feet,

EASTERLY, about 16 feet, and

SOUTHERLY, about 6.4 feet to an iron pin set at the westerly face of said wall; thence continuing

SOUTHERLY, more or less, along the westerly face of the aforementioned wall about 51 feet to an angle point in the wall; thence continuing

SOUTHERLY, more or less, along said wall a distance of about 25 feet to an iron pin set at the westerly face of said wall, said iron pin being 75.37 feet on a bearing of S 21° 00' 01" E, from the last mentioned iron pin; thence

NORTHEASTERLY, N 30° 24' 34" E, a distance of 62.37 feet to an iron pin set,

S 88° 10' 35" W, a distance of 11.14 feet to an iron pin set,

N 29 ° 55' 13" W, a distance of 13.01 feet to an iron pin set,

N 35° 19' 04" W, a distance of 12.82 feet to an iron pin set, and

N 11° 33' 48" W, a distance of 18.18 feet to a drill hole set; thence continuing along the edge of exposed wall;

NORTHEASTERLY, more or less, a distance of about 14 feet to a point,

NORTHWESTERLY, more or less, a distance of about 3 feet to a point,

SOUTHWESTERLY, more or less, a distance of about 14 feet to a point,

NORTHWESTERLY, more or less, a distance of about 12 feet to the southeasterly corner of the Francis Gatehouse, said corner bearing N 36° 56' 54" W, and being 15.26 feet distant from the last mentioned drill hole; thence running along the northeasterly face of the Francis Gatehouse

N 27° 26' 58" W, a distance of 13.41 feet to the northeasterly corner thereof; thence running along the back of the exposed granite wall

N 17° 56' 25" W, a distance of 9.09 feet to a drill hole set in the bottom step of some granite steps; thence continuing along the back edge of the wall

NORTHWESTERLY, more or less, a distance of about 32 feet to a point on the southerly wall of the Locking Gatehouse; thence running along the face of the north end of the Gatehouse as follows:

N 62° 43' 24" E, a distance of about 7 feet to the northeasterly corner of the Gatehouse,

N 27° 16' 45" W, a distance of 16.06 feet to the northerly corner of the Gatehouse,

S 62° 43' 24" W, a distance of about 8.7 feet to a point on the northerly face of the Locking Gatehouse, said point being at the back of the exposed granite wall as hereinbefore mentioned; thence running along the back of said wall

NORTHWESTERLY, more or less, a distance of about 0.7 feet to a drill hole set, said drill hole bearing S 66° 57' 39" W, and being 8.71 feet distant from the aforementioned northerly corner of the Locking Gatehouse; thence continuing along the back edge of said wall

N 22° 50' 38" W, a distance of 32.98 feet to a point, thence

WESTERLY, S 73° 44' 18" W, a distance of 38.05 feet to the point of beginning.

Containing 5,984 square feet of land, more or less.

Being shown as Guard Locks - Lock Chamber, on sheet 4 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

All six parcels are a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with the Middlesex Northern District Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 2,839 square feet, more or less

Interest: Easement

Date: January 27, 1994

TRACT 111-09

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Western Canal, so called, known and numbered as 501 Dutton Street and further bounded and described as follows:

Beginning at the northwesterly corner of Dutton Street and Hayden Street, said corner being the southeasterly corner of the parcel described; thence along the northwesterly line of Hayden Street

S 80° 30' 30" W, a distance of 150.82 feet to the easterly line of Worthen Street; thence along said Worthen Street

N 09° 34' 16" W, a distance of 17.24 feet to a point at the back edge of the southeasterly granite wall of the Western canal; thence along said canal wall

N 80° 23' 13" E, a distance of 154.75 feet to a point on the westerly line of Dutton Street; thence along said Dutton Street

SOUTHERLY, more or less, by a curve to the right having a radius of 1,210.46 feet, an arc length of 18.01 feet, to the point of beginning.

Containing 2,839 square feet of land, more or less.

Being shown as Parcel 24 on sheet 29 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 0.23 of an acre, more or less

Interest: Easement

Date: February 2, 1994

TRACT 111-17

Four certain parcels of land located in Lowell, Middlesex County, Massachusetts along the Hamilton Canal, so called, and known and numbered as 171.1 Jackson Street and further bounded and described as follows:

PARCEL I:

Beginning at the southwesterly corner of the parcel, said corner bearing N 12° 38' 52" W, and being 23 feet distant from the northerly line of Jackson Street; thence running along the easterly line of land now or formerly of James T. Lichoulas, Trustee of Appleton Trust

N 12° 38' 52" W, a distance of 10.91 feet to a cut set at the face of a concrete wall; thence running along the southerly line of land now or formerly of the Proprietors of Locks and Canals and along said wall

N 84° 56' 46" E, a distance of 48.75 feet to a drill hole set at the corner of said wall; thence running along the easterly line of land now or formerly of the Proprietors of Locks and Canals

N 02° 30' 39" E, a distance of 17.68 feet to a point at the Hamilton Canal; thence running along the southerly side of the Hamilton Canal

N 86° 56' 46" E, a distance of 64.37 feet to a point on the northwesterly line of Parcel 5345C, as hereinafter described; thence running along said northwesterly line of Parcel 5345C by two courses as follows:

SOUTHWESTERLY, more or less, by a curve to the right having a radius of 142 feet, an arc length of 18.55 feet to a point of compound curvature, and

SOUTHWESTERLY, more or less, by a curve to the right having a radius of 98 feet, an arc length of 34 feet to a point at the southeasterly corner of Parcel 5345B as hereinafter described; thence running along the easterly line of Parcel 5345B

N 12° 38' 52" W, a distance of 5.50 feet to a point; thence running along the northerly line of Parcel 5345B, said line being 23 feet distant from and parallel with the northerly line of Jackson Street

S 77° 21' 08" W, a distance of 67 feet to the point of beginning.

Containing 1,438 square feet of land, more or less.

Being shown as Parcel 5345A on sheet 15 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 29 June 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

PARCEL II:

Beginning at the northwesterly corner of the parcel, said corner being the southwesterly corner of Parcel 5345A as hereinbefore described; thence running along the southerly and easterly line of Parcel 5345A by two courses as follows:

N 77° 21' 08" E, a distance of 67 feet to a point, and

S 12° 38' 52" E, a distance of 5.50 feet to a point at land now or formerly of James T. Lichoulas, Trustee of Appleton Trust; thence running by land now or formerly of said James T. Lichoulas

S 77° 21' 08" W, a distance of 67 feet to a point on the easterly line of other land owned now or formerly by James T. Lichoulas, Trustee of Appleton Trust; thence along said easterly line of Lichoulas

N 12° 38' 52" W, a distance of 5.50 feet to the point of beginning.

Containing 368.5 square feet of land, more or less.

Being shown as Parcel 5345B on sheet 15 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 29 June 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

PARCEL III:

Beginning at the southwesterly corner of the parcel, said corner being the southeasterly corner of parcel 5345B as hereinbefore described; thence along the southerly line of Parcel 5345A by two courses as follows:

NORTHEASTERLY, more or less, by a curve to the left having a radius of 98 feet, an arc length of 34 feet to a point of compound curvature; and

NORTHEASTERLY, more or less, by a curve to the left having a radius of 142 feet, an arc length of 19.29 feet to a point at the Hamilton Canal; thence along the southerly line of said Hamilton Canal

N 77° 21' 08" E, a distance of 45 feet to a point; thence by land now or formerly of the Proprietors of Locks and Canals

S 20° 51' 08" W, a distance of 20 feet to a point on the northerly line of land now or formerly of James T. Lichoulas, Trustee of Appleton Trust; thence along said northerly line of Lichoulas

S 77° 21' 08" W, a distance of 84 feet to the point of beginning.

Containing 960 square feet of land, more or less.

Being shown as Parcel 5345C on sheet 15 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 29 June 1993 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

PARCEL IV:

Beginning at the southwesterly corner of the parcel, said point being the southeasterly corner of Parcel 5345C as hereinbefore described; thence along the easterly line of Parcel 5345C

N 20° 51' 08" E, a distance of 17.87 feet to a point at the Hamilton Canal; thence running along the back edge of the southerly wall of said canal by five courses as follows:

N 77° 46' 01" E, a distance of 33.52 feet to a punch mark set at the edge of a steel bridge girder,

N 76° 53' 30" E, a distance of 21.79 feet to another punch mark set at the edge of a steel bridge girder,

N 77° 16' 27" E, a distance of 59.96 feet to a cut set at the back edge of the wall,

N 77° 29' 54" E, a distance of 256.02 feet to a drill hole set at the back edge of the wall,

N 76° 33' 10" E, a distance of 107.84 feet to a point at land now or formerly of Courier Citizen company; thence by the westerly line of land of said Courier Citizen Company

S 12° 38' 52" E, a distance of 15.80 feet to a point at land now or formerly of James T. Lichoulas, Trustee of Appleton Trust; thence running by the northerly line of land of said James T. Lichoulas, Trustee

S 77° 21' 08" W, a distance of 588.99 feet to the point of beginning.

Containing 8,637 square feet of land, more or less.

Being shown as Parcel 5345D on sheet 15 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic

Engineering and Survey Consultants, dated 29 June 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Interest: Easement

Date: April 14, 1994

TRACT 111-22

A certain parcel of land located southerly of the Western Canal, so called, and also located southerly of a certain parcel of land known and numbered 501 Dutton Street, being a portion of Hayden Street, in the City of Lowell, County of Middlesex and Commonwealth of Massachusetts, and further bounded and described as follows:

Beginning at a point at the intersection of the Northwesterly line of Hayden Street with the Northerly line of Worthen Street, said point being the Southerly corner of the parcel known as 501 Dutton Street, being owned by the Commonwealth of Massachusetts;

Thence, turning and running Northeasterly along said land of the Commonwealth of Massachusetts a distance of 150.82 feet, more or less to the Westerly line of Dutton Street;

Thence, turning and running along said line of Dutton Street 10 feet, more or less to a point in the middle of Hayden Street;

Thence, turning and running Southwesterly in a straight line to a point located at the intersection of Hayden Street with the Northerly line of Worthen Street;

Thence, turning and running along said Worthen Street a distance of 10 feet, more or less, to the point of beginning.

The above described land is shown on the following plans:

Sheet 29 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69; and

Sheet 4 of a set of plans entitled "The Commonwealth of Massachusetts Plan of Road in the City of Lowell, Middlesex County Laid Out as a City Highway by the Department of Public Works" and prepared by Howard, Needles, Tammen & Bergendoff, dated September 25, 1985 and recorded with said Registry of Deeds in Plan Book 150, Plan 53.

Said property being owned by the Commonwealth of Massachusetts by virtue of its Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 7,597 square feet, more or less

Interest: Easement

Date: January 27, 1994

TRACT 111-23

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Western Canal, so called, known and numbered as 139 Broadway and further bounded and described as follows:

Beginning at a drill hole set in the concrete sidewalk at the northeasterly corner of Suffolk Street and Broadway; thence running along the easterly line of Suffolk Street

N 11° 11' 30" W, a distance of 321.90 feet to a drill hole set at the southeasterly corner of Suffolk Street and Jefferson Street; thence running along the southerly line of Jefferson Street

N 78° 52' 10" E, a distance of 23.58 feet to a drill hole set on the westerly line of the Western Canal; thence running along the back edge of the concrete retaining wall of said Western Canal as follows:

S 11° 18' 00" E, a distance of 160.76 feet to a spike set, and

S 11° 11' 27" E, a distance of 161.69 feet to the northerly line of Broadway; thence running along said northerly line of Broadway

S 80° 04' 33" W, a distance of 23.88 feet to the point of beginning.

Containing 7,597 square feet of land, more or less.

Being shown as Parcel CB-C, Lot A on sheet 28 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 6,450 square feet, more or less

Interest: Easement

Date: January 27, 1994

TRACT 111-24

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Western Canal, so called, known and numbered as 125 Broadway and further bounded and described as follows:

Beginning at a drill hole set in the granite curb at the northwesterly corner of Broadway and Lewis Street; thence running along the northerly line of Broadway

S 80° 04' 33" W, a distance of 25 feet, more or less, to the easterly shoreline of the Western Canal; thence running along said easterly shoreline of the Western Canal

NORTHERLY, more or less, a distance of 328 feet, more or less, to a point on the southerly line of Jefferson Street; thence along said line of Jefferson Street

N 78° 52' 10" E, a distance of 24 feet, more or less, to a spike set at the corner of Lewis Street; thence running along the westerly line of Lewis Street

S 11° 11' 30" E, a distance of 324.02 feet to the point of beginning.

Containing 6,450 square feet of land, more or less.

Being shown as Parcel CB-D, Lot B on sheet 28 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 6 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 0.09 of an acre, more or less

Interest: Easement

Date: February 2, 1994

TRACT 111-26

A certain parcel of land located in Lowell, Middlesex County, Massachusetts along the Pawtucket Canal, so called, and further bounded and described as follows:

Beginning at an iron pin set at the most westerly corner of the parcel, said pin being at the northeasterly corner of Parcel CB-A, as shown on the plan hereinafter described, and being at the back edge of the southerly granite wall of the Pawtucket Canal; thence along the back edge of said canal wall

N 57° 32' 42" E, a distance of 42.67 feet to a point on the southwesterly location line of the Boston and Maine Railroad; thence along said railroad location line as follows:

SOUTHEASTERLY, more or less, by a curve to the right having a radius of 967.73 feet, an arc length of 41.01 feet to a point,

N 51° 44' 05" E, a distance of 10.85 feet to an iron pin set, and

SOUTHEASTERLY, more or less, by a curve to the right having a radius of 977.73 feet, an arc length of 21.57 feet to an iron pin set at land now or formerly of Thomas M. Hughes; thence along the northwesterly line of land of said Hughes

S 51 44' 05" W, a distance of 95.31 feet to a point on the easterly line of Parcel CB-A; thence along said easterly line of Parcel CB-A

N 22° 45' 06" W, a distance of 64.06 feet to the point of beginning.

Containing 4,011 square feet of land, more or less.

Being shown as Parcel 2B/2C-1/2C-2 on sheet 10 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 2 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 937 square feet, more or less

Interest: Easement

Date: February 3, 1994

TRACT 111-32

A certain parcel of land with buildings, improvements, structures and fixtures thereon, commonly known as the Swamp Locks Gate House, located in Lowell, Middlesex County, Massachusetts over the Lower Pawtucket Canal, so called, and further bounded and described as follows:

Beginning at the northwesterly corner of the parcel, said corner being a point along the southerly line of Parcel CB-G, as shown on the plan hereinafter described, bearing N 79° 49' 52" E, and being 3.15 feet distant from a drill hole set at an angle in the said southerly line of Parcel CB-G; thence along said line of Parcel CB-G

N 79° 49' 52" E, a distance of 3.52 feet to a point; thence running along the edge of a steel grate footbridge as shown on said plan

S 04° 25' 13" E, a distance of 64.47 feet to the northerly wall of the northerly gate house; thence running along the wall of said gate house as follows:

N 85° 34' 47" E, a distance of 11.22 feet to a corner,

S 04° 25' 13" E, a distance of 10.50 feet to a corner,

S 85° 34' 47" W, a distance of 9.75 feet to a corner and

S 04° 25' 13"E, a distance of 30.06 feet to a point 0.30 feet beyond the southeasterly corner of the northerly gate house; thence

S 85° 34' 20" W, a distance of 2 feet to a point 1.78 feet distant from the northeasterly corner of the southerly gate house and along the prolongation of the easterly wall thereof; thence running to and along the easterly wall of said southerly gate house as follows:

S 03° 45' 33" E, a distance of 20.14 feet to a corner,

S 86° 14' 27" W, a distance of 12.42 feet to a corner, and

N 03° 45' 33" W, a distance of 18.36 feet to a corner, and

N 86° 14' 27" E, a distance of 6.32 feet to a point on the northerly wall of said southerly gate house, said point being along the prolongation of the westerly wall of the northerly gate house, and 2.01 feet distant therefrom; thence running to and along the wall of said northerly gate house as follows:

N 04° 25' 13" W, a distance of 31.77 feet to a corner,

S 85° 34' 47" W, a distance of 3.93 feet to a corner,

N 04° 25' 13" W, a distance of 10.50 feet to a corner, and

N 85° 34' 47" E, a distance of 7.08 feet to a point on the northerly wall of the northerly gate house at the westerly edge of the steel grate footbridge; thence running along the westerly edge of said footbridge

N 04° 25' 13" W, a distance of 64.11 feet to the point of beginning.

Containing 937 square feet of land, more or less.

Being shown as Swamp Locks Gate House on sheet 12 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 2 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 875 square feet, more or less

Interest: Easement

Date: February 3, 1994

TRACT 111-33

Two certain parcels of land with improvements, structures and fixtures thereon, commonly known as the Swamp Locks Dam North and South, located in Lowell, Middlesex County, Massachusetts over the Lower Pawtucket Canal, so called, and further bounded and described as follows:

PARCEL I:

Beginning at the southeasterly corner of the dam, said corner being the northeasterly corner of the northerly gate house as shown on the plan hereinafter described; thence along the northerly wall of said northerly gate house

S 85° 34' 47" W, a distance of 14 feet, more or less, to the face of the dam, said face being about one foot easterly from and parallel with the westerly edge of the steel grate footbridge as shown on said plan; thence running along the face of the dam

N 04° 25' 13" W, a distance of 61 feet, more or less, to the face of a concrete wall; thence running along said concrete wall

EASTERLY, NORTHERLY and EASTERLY, all of said directions being more or less, a distance of 14 feet more or less to a point along the wall at the toe of the dam; thence running along the toe of the dam

S 04° 25' 13" E, a distance of 64 feet, more or less, to the point of beginning.

Containing 875 square feet of land, more or less.

PARCEL II:

Beginning at the northwesterly corner of the dam, said corner being 2.5 feet easterly from a westerly wall of the northerly gate house as shown on the plan hereinafter described; thence running along the northerly line of the dam, said line being along a southerly wall in the aforesaid northerly gate house

N 85° 34' 47" E, a distance of 28 feet, more or less, to the northeast corner of the dam; thence running across the toe of the dam

S 04° 25' 13" E, more or less, a distance of 30 feet, more or less, to the southeast corner of the dam; thence along the northerly face a granite wall

S 85° 34' W, more or less, a distance of 28 feet, more or less, to the southwest corner of the dam, said corner being a point on the southerly wall of aforesaid northerly gate house; thence running along the face of the dam, said face being 2.5 feet easterly from and parallel with a westerly wall of said gate house

N 04° 25' 13" W, a distance of 30 feet, more or less, to the point of beginning.

Containing 840 square feet of land, more or less.

Both Parcels I and II being shown as Swamp Locks Dam/North and Swamp Locks Dam/South on sheet 12 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 2 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Area: 11,685 square feet, more or less

Interest: Easement

Date: February 3, 1994

TRACT 111-34

All that improvement and/or air rights with any structures and fixtures thereon, commonly known as the Swamp Locks Lock Chambers, located in Lowell, Middlesex County, Massachusetts over the Lower Pawtucket Canal, so called, and further bounded and described as follows:

Beginning at a cross-cut set at the most westerly corner of the parcel, said cross-cut being at the back edge of the southerly granite wall of the Pawtucket Canal and being on the northerly line of land of Parcel CB-I as shown on the plan hereinafter described; thence crossing the headwaters of the Swamp Locks and running

N 60° 11' 35" E, a distance of 45.57 feet to a cut set on the northerly face of a concrete buttress; thence along the northerly face of said buttress

N 86° 14' 27" E, a distance of 7.43 feet to the westerly face of the Swamp Locks Gate House; thence running along the walls of said Gate House:

S 03° 45' 33" E, a distance of 4.26 feet to a corner,

N 86° 14' 27" E, a distance of 12.42 feet to a corner, and

N 03° 45' 33" W, a distance of 1.17 feet to a point on the easterly wall of said Swamp Locks Gate House; continuing,

N 03° 45' 33" W, a distance of 18.96 feet to a point at the northerly face of the southerly granite wall of the Lower Pawtucket Canal; thence running along said granite wall as follows:

N 85° 34' 20" E, a distance of 46.21 feet to a cut set in the face of said wall,

N 84° 43' 16" E, a distance of 43.12 feet to a cut set in the face of said wall, and

N 89° 50' 16" E, a distance of 20.87 feet to a cut set in the face of said wall; thence running along the northerly face of the southerly granite wall of the Lower Pawtucket Canal and thence crossing a twenty foot passageway

N 86° 13' 40" E, a distance of 66.78 feet to a point on the easterly line of said twenty foot passageway; thence running along the easterly line of said twenty foot passageway

N 09° 30' 31" W, a distance of 3.95 feet to the southerly shoreline of the Lower Pawtucket Canal; thence running along said southerly shoreline as follows:

N 85° 27' 15" E, a distance of 41.46 feet to a point,

N 88° 55' 33" E, a distance of 80.01 feet to a point, and

S 06° 40' 48" E, a distance of 11.18 feet to a point at the bottom of the Swamp Locks Lower Lock Chamber; thence running along said Lower Lock Chamber

S 84° 08' 49" W, a distance of 48.05 feet to a point; thence running as follows:

S 00° 25' 22" E, a distance of 27.89 feet to a point on the northerly line of land now or formerly of the Pellon Corporation; thence along the line of said Pellon Corporation

S 77° 16' 35" W, a distance of 66.89 feet to a point on the easterly line of a twenty foot passageway leading to Jackson Street; thence along the easterly line of said passageway

N 13° 10' 56" W, a distance of 11.82 feet to a point at the southerly wall of the Swamp Locks Chamber; thence along the southerly wall of the Swamp Locks Lower Locks Chamber as follows:

S 81° 09' 40" W, a distance of 52.56 feet to a drill hole set in the face of a concrete wall, and

N 01° 48' 53" W, a distance of 7.55 feet to an iron pin set at the back edge of the southerly granite wall of the Swamp Locks Upper Chamber; thence running along the back edge of said granite wall as follows:

S 85° 46' 53" W, a distance of 139.78 feet

S 87° 04' 42" W, a distance of 49.47 feet to the point of beginning.

Containing 11,685 square feet of land, more or less.

Being shown as Swamp Locks-Lock Chamber on sheet 11 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 28 June 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

Purported Owner: Commonwealth of MA/DEM

Lowell Historic Preservation Commission

Interest: Easement

Date: June 29, 1992
Revised: February 3, 1994

TRACT 112-01

A certain parcel of land with buildings, structures and fixtures, thereon, commonly known as the Hamilton Gate House, located in Lowell, Middlesex County, Massachusetts over the Hamilton Canal, so called, and near Jackson Street and further bounded and described as follows:

Beginning at a point on the westerly line of the Hamilton Canal at the head of the Hamilton Wasteway, said point bearing northeasterly, more or less, and being 21.05 feet distant from the southeasterly corner of a building foundation, thence running along the westerly face of the Hamilton Gate House by land now or formerly of John Adden Furniture, Inc. N 12° 40' 17" W, a distance of 12.18 feet to the northwesterly corner of the gate house, said corner bearing southeasterly more or less and being 20.40 feet distant from the northeasterly corner of a building foundation; thence running the following two courses along the northerly and easterly faces of the Hamilton Gate House, by land now or formerly of John Adden Furniture, Inc.;

N 77° 19' 43" E, a distance of 21.18 feet to the northeast corner of said gate house,

S 12° 40' 17" E, a distance of 12.18 feet to the southeast corner of said gate house;

Thence, running across the canal along the southerly face of the gate house, by land now or formerly of John Adden Furniture, Inc., S 77° 19' 43" W, a distance of 21.18 feet to the point of beginning.

Containing 258 square feet of land, which is 0.01 of an acre, more or less.

Being shown as the Hamilton Gate House on sheet 16 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

Being a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

TRACT 112-04

The following three parcels of land, with the buildings thereon, located in Lowell, Middlesex County, Massachusetts and more particularly bounded and described as follows:

PARCEL I:

A certain parcel of land located on the Pawtucket Canal, so called, in Lowell, Middlesex County, Massachusetts and commonly known as the Lower Locks Dam, and further bounded and described as follows:

Beginning at a point at the southwesterly corner of the parcel, said point being two feet distant from and parallel with the westerly face of the Lower Locks Gatehouse, as hereinafter described; thence crossing the Pawtucket Canal and running along the face of the Lower Locks Dam

N 06° 25' 46" E, a distance of 87 feet, more or less, to a point at the northerly end of the dam; thence running along the northerly end of the Lower Locks Dam

EASTERLY, more or less, a distance of about 41 feet to the base of said Dam; thence crossing the Pawtucket Canal and running across the base of the dam

SOUTHERLY, more or less, a distance of about 98 feet to a point at the base of granite of the Lower Locks; thence running along the southerly line of the Lower Locks Dam, being at the base of granite of said Lower Locks

WESTERLY, more or less, a distance of about 46 feet to the point of beginning.

Containing 3,680 square feet of land, more less.

PARCEL II:

The land, with the buildings thereon, located on the Pawtucket Canal in Lowell, Middlesex County, Massachusetts and commonly known as the Lower Locks Gatehouse, and further bounded and described as follows:

Beginning at the southwesterly corner of the Lower Locks Gatehouse, as shown on the Plan hereinafter described; thence running along the westerly face of the Gatehouse, more or less, and across the Pawtucket Canal, by five courses as follows:

N 06° 25' 46" E, a distance of 64.78 feet to a point,

N 83° 34' 14" W, a distance of 2.50 feet to a point,

N 06° 25' 46" E, a distance of 12.25 feet to a point,

S 83° 34' 14" E, a distance of 2.50 feet to a point, and

N 06° 25' 46" E, a distance of 18.10 feet to the northwesterly corner of the Gatehouse, being at land now or formerly of the City of Lowell and known as the Rex lot; thence along the northerly face of the Lower Locks Gatehouse by land now or formerly of the City of Lowell

S 83° 34' 14" E, a distance of 7.50 feet to the northeasterly corner of the Gatehouse; thence running along the easterly face of said Gatehouse, and crossing the Lower Locks Dam, by five courses as follows:

S 06° 25' 46" W, a distance of 18.10 feet to a point,

S 83° 34' 14" E, a distance of 7.70 feet to a point,

S 06° 25' 46" W, a distance of 12.25 feet to a point,

N 83° 34' 14" W, a distance of 7.70 feet to a point, and

S 06° 25' 46" W, a distance of 64.78 feet to the southeasterly corner of the Lower Locks Gatehouse; thence along the southerly face of the gatehouse

N 83° 34' 14" W, a distance of 7.50 feet to the point of beginning.

Containing 838 square feet of land, more or less.

PARCEL III:

The land, with any buildings and fixtures thereon, located on the Pawtucket Canal in Lowell, Middlesex County, Massachusetts, commonly known as the Lower Locks Chambers, and more particularly bounded and described as follows:

Beginning at the most westerly corner of the parcel, said corner being a point on the northerly line of Parcel CB-H, as shown on the Plan hereinafter described, and bearing S 85° 57' 30" E, and being 49.55 feet distant from a drill hole set in the southwesterly end of a concrete wall; thence running to a point on the northerly side of the Lower Locks

N 12° 49' 10" E, a distance of 23.64 feet; thence running along the outer edge of the granite blocks

S 82° 56' 24" E, a distance of 17.44 feet to a point on the southerly prolongation of the westerly line of the Lower Locks Gatehouse; thence

N 06° 25' 46" E, a distance of 1.49 feet to the southwesterly corner of the Lower Locks Gatehouse; thence along the southerly face of said Gatehouse

S 83° 34' 14" E, a distance of 7.50 feet to the southeast corner of the Lower Locks Gatehouse; thence along the easterly wall of said Gatehouse

N 06° 25' 46" E, a distance of 4.76 feet to a point; thence along the northerly edge of the concrete capped wall of the Lower Locks

S 83° 18' 52" E, a distance of 126.25 feet to a point; thence along the northerly top edge of granite of the Lower Locks by three courses as follows:

N 89° 40' 25" E, a distance of 9.86 feet to a point,

S 82° 53' 58" E, a distance of 98.75 feet to a point, and

N 80° 11' 21" E, a distance of 11.35 feet to a point at the base of the granite blocks of the Lower Locks; thence running along the base of said blocks

S 06° 01' 39" W, a distance of 38.00 feet to an iron pin set at the base of the last granite stone on the southeasterly end of the Lower Locks, said iron pin being at an angle in the northerly line of Parcel C8-H as hereinbefore mentioned; thence running along the southerly line of the Lower Locks, being the northerly line of Parcel C8-H, by four courses as follows:

N 83° 10' 03" W, a distance of 136.39 feet to a drill hole set in granite,

N 83° 28' 56" W, a distance of 110.00 feet to an iron pin set,

N 44° 46' 55" W, a distance of 8.86 feet to an x-cut set in granite, and

N 85° 57' 30" W, a distance of 20.24 feet to the point of beginning.

Containing 9,127 square feet of land, more or less.

All three parcels are shown on sheet 14 of a set of plans entitled "Lowell Canal System, Lowell Heritage State Park, Lowell, Massachusetts" prepared by Atlantic Engineering and Survey Consultants, dated 1 July 1983 and recorded with the Middlesex Northern District Registry of Deeds at Plan Book 157, Plan 69.

All three parcels are a portion of the premises taken by the Commonwealth of Massachusetts by Order of Taking dated December 1, 1986 and recorded with said Registry of Deeds at Book 3830, Page 70.

DISCLAIMER:

Parcel: CB-G - See Fig# 0013
Researched Owner: Commonwealth owns in fee.
Researched Easement: NPS holds an easement for access, construction and maintenance of improvements.
Parcel: Swamp Locks Dam North - See Fig# 0012 - F20
Researched Owner: Proprietors owns Swmap Locks Dam (North).
Researched Easement: CW has permanent and exclusive easement for supplemental maintenance, preservation, conservation, landscaping and erection of structures. Boott has an easement for the right to access, operate and maintan. NPS holds an easement for access, construction and maintenance of improvements, as well as to run boat tourns.
Parcel: Swamp Locks Gatehouse - See Fig# 0012 - F20
Researched Owner: Commonwealth(CW) owns in fee buildings, structures and fixtures above 89.2ft. MSL except structures/equipment used for hydropower generation. Proprietors owns all structures and fixtures below 89.2ft. MSL.
Researched Easement: CW has permanent easement to all canal walls, beds and bottoms supporting said structure under 89.2ft MSL. Boott has easement for the right to access,operate and maintain. NPS holds easement for access,construction, maintenance of improvements.
Parcel: Swamp Locks - Locks Chamber - See Fig# 0011 - F20
Researched Owner: Proprietors owns Swamp Locks Lock Chambers in fee.
Researched Easement: CW has permanent and exclusive easement for supplemental maintenance, preservation, conservation, landscaping and erection of structures. Boott has easement for right to access,operate and maintain. NPS holds easement for access,construction,maintenance of improvements.
Parcel: Swamp Locks Dam South - See Fig# 0012 - F20
Researched Owner: Proprietors owns Swamp Locks Dam in fee.
Researched Easement: CW has permanent and exclusive easement for supplemental maintenance, preservation, conservation, landscaping and erection of structures. Boott has easement for right to access, operate and maintain. NPS holds easement for access,construction and maintenance of improvements, as well as to run boat tours.
Parcel: CB-1 - See Fig# 0011
Researched Owner: Commonwealth(CW) owns in fee except the right to use or maintain for hydropower.
Researched Easement: None Identified
Parcel: 5345 C - See Fig# 0015
Researched Owner: Commonwealth owns in fee.
Researched Easement: NPS holds an easement for access, construction, and maintenance of improvements.
Parcel: 5345 A - See Fig# 0015

1 Introduction and Background

Boott Hydropower, LLC (Boott or Licensee) is the Licensee, owner, and operator of the 20.2-megawatt (MW) Lowell Hydroelectric Project (Project or Lowell Project) (FERC No. 2790). Boott operates and maintains the Project under a license from the Federal Energy Regulatory Commission (FERC or Commission). The Project's existing license expires on April 30, 2023. Boott is pursuing a new license for the Project using the Commission's Integrated Licensing Process (ILP) as defined in 18 Code of Federal Regulations (C.F.R.) Part 5.

In accordance with 18 C.F.R. § 5.15, Boott has conducted studies as provided in the study plan and schedule approved in the Commission's March 13, 2019 Study Plan Determination (SPD) for the Project.[1] This report describes the methods and results of the approved Water Level and Flow Effects on Historic Resources Study conducted in support of a new license for the Project.

1.1 Project Description and Background

The Lowell Project is located at river mile (RM) 41 on the Merrimack River in the City of Lowell in Middlesex County, Massachusetts, with a headpond extending approximately 23 miles upstream into Hillsborough County, New Hampshire. The existing Lowell Project consists of:

1) A 1,093-foot-long, 15-foot-high masonry gravity dam (Pawtucket Dam) that includes a 982.5-foot-long spillway with a crest elevation of 87.2 feet (ft) National Geodetic Vertical Datum 1929 (NGVD 29) topped by 5-foot-high pneumatically-operated crest gates deployed in five independently-operable zones;
2) A 720-acre headpond with a normal maximum water surface elevation of 92.2 ft NGVD 29;
3) A 5.5-mile-long canal system which includes several small dams and gatehouses;
4) A powerhouse (E.L. Field) which uses water from the Northern Canal and contains two turbine-generator units with a total installed capacity of 15.0 MW;
5) A 440-foot-long tailrace channel;
6) Four powerhouses (Assets, Bridge Street, Hamilton, and John Street) housed in nineteenth century mill buildings along the Northern and Pawtucket Canal systems containing 15 turbine-generator units with a total installed capacity of approximately 5.1 MW;
7) A 4.5-mile-long, 13.8-kilovolt transmission line connecting the powerhouses to the regional distribution grid;

[1] The Commission issued a Revised Process Plan and Schedule on June 12, 2020.

8) Upstream and downstream fish passage facilities including a fish elevator and downstream fish bypass at the E.L. Field powerhouse, and a vertical-slot fish ladder at the Pawtucket Dam; and

9) Appurtenant facilities.

At the normal pond elevation of 92.2 ft NGVD 29[2] (crest of the pneumatic flashboards), the surface area of the headpond encompasses an area of approximately 720 acres. The gross storage capacity between the normal surface elevation of 92.2 ft and the minimum pond level of 87.2 ft is approximately 3,600 acre-ft. The Project operates essentially in a run-of-river (ROR) mode using automatic pond level control and has no usable storage capacity.

The Project's primary features are located along the Merrimack River in the City of Lowell, Massachusetts. The City of Lowell was founded in the early 1820s by Boston merchant capitalists and became one of the most significant planned industrial cities in America (Hay 1991). Lowell's factory system, which used the waterpower of the Merrimack River, incorporated new technologies to provide for the mass production of cotton cloth in mills throughout the city (National Park Service [NPS] 1981). Lowell established the pattern for large-scale waterpower development for the next 50 years (Hay 1991).

Several Project facilities are located within overlapping locally, state, and nationally designated parks and historic properties and/or preservation districts. The Project's Pawtucket Dam and E.L. Field Powerhouse are located along the mainstem of the Merrimack River. The Project's two-tiered network of man-made canals extends throughout downtown Lowell. The 5.5-mile-long canal system provides flow to the Project's Hamilton, Assets, Bridge Street, and John Street developments. The Hamilton, Assets, Bridge Street, and John Street power stations and turbines are housed in large former mill buildings. The mill buildings are not included in the Project; the Project Boundary includes only the turbines and associated equipment at these downtown mill sites. In addition to the Pawtucket Dam and hydroelectric developments, the Project also includes miscellaneous civil works in the City of Lowell, including the Guard Lock and Gates, Moody Street Feeder Gatehouse, Lawrence Dam, Hall Street Dam, Tremont Wasteway, Lower Locks and Dam, Swamp Locks and Dam, Merrimack Dam and Merrimack Gate, Rolling Dam, and the Boott Dam.

The canal system, the downtown mill sites, and many of the Project's civil works, are contributing resources to Lowell Locks and Canals National Historic Landmark (NHL) District. The canal system and many Project facilities are also located within the Lowell National Historical Park (LNHP) managed by the NPS and the larger Lowell Historic Preservation District. The LNHP was established by Congress in 1978 to "preserve and interpret the nationally significant historical and cultural sites, structures, and districts in Lowell, Massachusetts, for the benefit and inspiration of present and future generations." The park is by design a partnership park in which federal, state, and local governments as

[2] Elevations throughout this study are reported or have been converted to the National Geodetic Vertical Datum 1929 (NGVD 29).

well as the private sector and local community carry out the legislative intent of the park unit. The Lowell National Historical Park is also listed on the National Register of Historic Places, and certain properties within the park overlap with properties in the NHL District.

The Lowell Heritage State Park, established in 1974 as a precursor to the LNHP, is also located within the City of Lowell and is comprised of linear greenways along the Merrimack River and canal system and a collection of historic buildings and structures related to the industrial development of the city. These buildings and structures include Project features and properties located within the NHL District. The Lowell Heritage State Park is operated by the Massachusetts Department of Conservation and Recreation (MADCR) and features exhibits created in partnership with the NPS (MADCR 2018). With the exception of the Rynne Bathhouse, all of the built resources within the Lowell Heritage State Park fall within the Lowell Historic District, designated by the City of Lowell to "…ensure that development activities within the district are consistent with the preservation of its 19th century setting" (MADCR 2014). Portions of the Lowell Heritage State Park also overlap with the Lowell Locks and Canals NHL District and the LNHP.

1.2 Study Development

On April 30, 2018, Boott initiated the ILP by filing a Pre-Application Document (PAD) and Notice of Intent (NOI) with the Commission. Major ILP milestones to-date are presented in Table 1-1.

Table 1-1. Major ILP Milestones Completed

Date	Milestone
April 30, 2018	PAD and NOI Filed
June 15, 2018	Scoping Document 1 (SD1) Issued by FERC
July 17, 2018	FERC Agency and Public Scoping Meetings Conducted
September 27, 2018	Scoping Document 2 (SD2) Issued by FERC
September 28, 2018	Proposed Study Plan (PSP) Filed
October 18 & 19, 2018	PSP Meeting Conducted
January 28, 2019	Revised Study Plan (RSP) Filed
March 13, 2019	FERC Issued SPD
February 25, 2020	Initial Study Report (ISR) Filed
March 11, 2020	ISR Meeting
June 12, 2020	FERC Issued Revised Process Plan and Schedule
December 2, 2020	Draft License Application Filed
February 25, 2021	Second ISR Filed
April 30, 2021	Final License Application Filed

Boott has continued consultation with stakeholders regarding the approved studies as required by the Commission's SPD. In accordance with the schedule presented in the Revised Study Plan (RSP), Boott has also provided stakeholders with Quarterly ILP Study Progress Reports that include a description of study activities conducted during the previous quarter, activities expected to occur in the next quarter, and identified variances from the approved study plan.

The NPS previously indicated that changing water levels and flows in the Project's canal system have the potential to adversely affect historic canal structures. To document water levels under a range of operating conditions, Boott deployed pressure transducers (level loggers) in the canal system to record water level fluctuations at 15-minute intervals. By letter dated May 5, 2019, Boott consulted with the NPS regarding the specific locations for level logger deployment. In June 2019, level loggers were deployed at 10 locations in the canal system. Data from the level loggers were downloaded on an approximate monthly basis.

On December 18, 2019, Boott held a Study Workshop to discuss the Water Level and Flow Effects Study; Recreation and Aesthetics Study; Historically Significant Waterpower Equipment Study; and the Resources, Ownership, Boundaries, and Land Rights Study. During the workshop, the NPS clarified that their interest was related to the effects of the Pawtucket Dam pneumatic crest gate system that became operational in 2018. The NPS was concerned that the new pneumatic crest gate could increase flows to the downtown canal system and that higher flows could have the potential to adversely affect historic structures. During the December 18, 2019 Study Workshop, Boott explained that water levels in the downtown canal system are not affected by the crest gate and that any effects would be limited to structures along the Northern Canal and the Upper Pawtucket Canal (extending upstream from the Guard Lock Gate Complex to the mainstem of the Merrimack River). Given that water levels in the downtown canal system are not affected by crest gate operations, the NPS agreed that the historic resources along the Northern Canal and Upper Pawtucket Canal should be the focus of the Water Level and Flow Effects Study. Therefore, the NPS and Boott agreed that Boott should relocate level loggers to the Upper Pawtucket Canal and Northern Canal and remove the remaining level loggers from the downtown canal system. Boott relocated the level loggers in March 2020 and recorded water level fluctuations in the Upper Pawtucket Canal and Northern Canal in 15-minute intervals through late September 2020. During the 2020 deployment period, Boott recorded a wide range of flows in the Upper Pawtucket Canal and Northern Canal, including high flow events during the spring freshet and low flow events during the summer and early fall of 2020. Boott believes that this range of flows is appropriate to analyze potential Project-related water level and flow effects on historic structures in the Upper Pawtucket and Northern canals. Boott utilized the level logger data from the 2020 deployment period, Project operation data, existing drawings, and field observations to assess potential effects.

2 Study Goals and Objectives

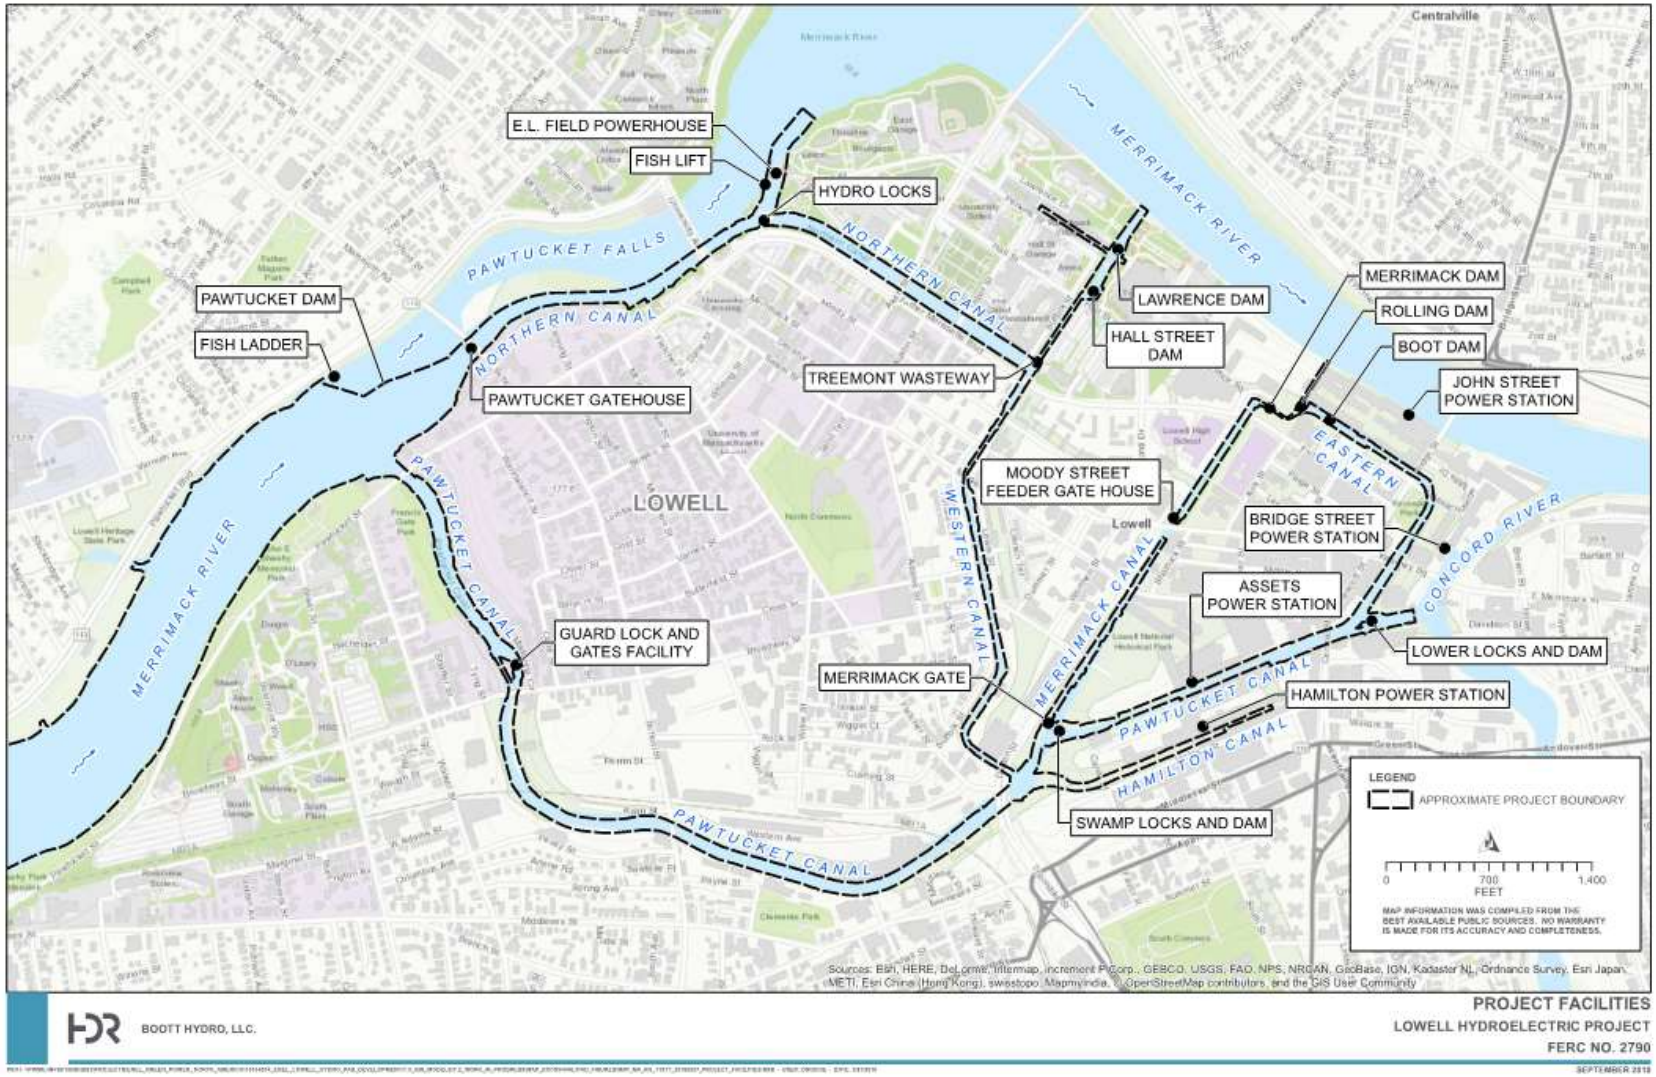
The goal of this study is to assess the potential effect of water level fluctuations within the headpond, Northern Canal, and the Pawtucket Canal (extending upstream from the Guard Lock Gate Complex to the mainstem of the Merrimack River) on the historic structures including the Pawtucket Gatehouse, the Waste Gate Building, the Guard Lock Gate Complex structures, and the Great Wall. The specific objectives of this study are as follows:

- Evaluate how Project operations, including manipulation of the new crest gate system, canal head gates, spillways, locks, fish passage structures, and generating units will change water levels in the Upper Pawtucket and Northern Canals;
- Determine the extent to which water flows or elevations are having an effect on historic resources;
- Conduct a structural assessment of the Great River Wall; and
- Identify potential impacts of current Project operations on nationally significant historic resources, including a structural assessment of the Great River Wall.

3 Study Area

In accordance with the Commission's SPD, the study area for the Water Level and Flow Effects on Historic Resources includes the Projects canal system and associated Project infrastructure within the FERC Project Boundary in the City of Lowell, limited to the Northern Canal from the canal headworks to the E.L. Field Powerhouse not including the portion of the Northern Canal downstream of the Hydro Locks. Also included in the study area is the Upper Pawtucket Canal from the confluence with the Merrimac River downstream to the Guard Lock Gate Complex (Figure 3-1) and the portion of the Project headpond in the proximity of the Pawtucket Dam.

Figure 3-1. Study Area for the Water Level and Flow Effects on Historic Resources Study Report



4 Methodology

4.1 Document Review of Existing Conditions

Boott reviewed available architectural and engineering evaluations of historic canal structures available from the NPS and other stakeholders, including documentation of previous maintenance and repairs to characterize existing conditions. Based on this document review, Boott identified properties that have previously been affected by water level or flow conditions. Copies of these documents are included in Appendix A of this study report.

4.2 Site Visit to Document Existing Conditions

The approved Water Level and Flow Effects Study Plan directed Boott to conduct a site visit with the NPS, to identify locations where fluctuating water levels or flows have previously caused adverse effects to historic structures along the canal system. As proposed by Boott, the intention of this field visit was to collect additional information from NPS staff who may have observed or documented potential adverse effects associated with Project-related flows or water levels, and to identify specific structures (or components of structures) that are of interest to the NPS. However, due to the ongoing COVID-19 pandemic, Boott sought alternatives to in-person meetings and field visits to protect the health and safety of all parties.

Accordingly, Boott consulted with the NPS via letter dated January 4, 2021 regarding previously documented issues related to Project-related flow effects or changing water levels along the canal system. Boott sought the NPS's assistance in identifying historic canal structures along the Upper Pawtucket and Northern Canals that have purportedly been affected by Project-related water levels or flows. Specifically, Boott sought any records of previous damage, maintenance, or repairs to structures along the Upper Pawtucket or Northern canals that have resulted from Project-related flows or water levels. Boott requested the NPS's assistance in identifying any other known issues related to water levels and flow effects on specific structures along these canals.

Boott conducted a site visit to historic canal structures with input from NPS to identify issues previously noted by the NPS related to the flow and water levels on historic structures. Due to COVID-19 guidance and restrictions, the site visit was conducted by Boott independently. The site visit was conducted on January 27, 2020 by Boott to visually assess the effects of water level fluctuations on the historic structures associated with the Northern and Upper Pawtucket Canals and to collect additional data in support of this study.

NPS provided written comments on February 3, 2021 in response to Boott's request for information. Following receipt of that information from NPS, Boott performed an additional

data collection site visit on February 15, 2021 to collect additional elevation information for the historic structures detailed by NPS.

4.3 Canal Water Level Monitoring

To assess water levels under a range of operating conditions, Boott installed pressure transducers (level loggers) at four locations within the canal system that were identified in consultation with the NPS, and an additional atmospheric logger deployed near the E.L. Field Powerhouse (for calibration and barometric pressure correction).

The level loggers were installed on March 10, 2020 and were placed at a depth where they would remain below the water level during all field conditions during the study period. Accordingly, each installation established a sound, initial reference depth to which relative change (increase/decrease in water depth) was then recorded.

Additionally, each level logger was placed in an inconspicuous location on the channel bottom or tethered with weights to a non-movable object (i.e. rock, handrail, or tree). Each level logger recorded Kilopascal (kPa) pressure and Fahrenheit (°F) water temperature at 15-minute intervals. Pressure was converted to a relative sensor depth using Hoboware Pro™ software by Onset®, and the loggers have a stated operational range of 0 to 30 ft and an accuracy of ±0.03 ft.

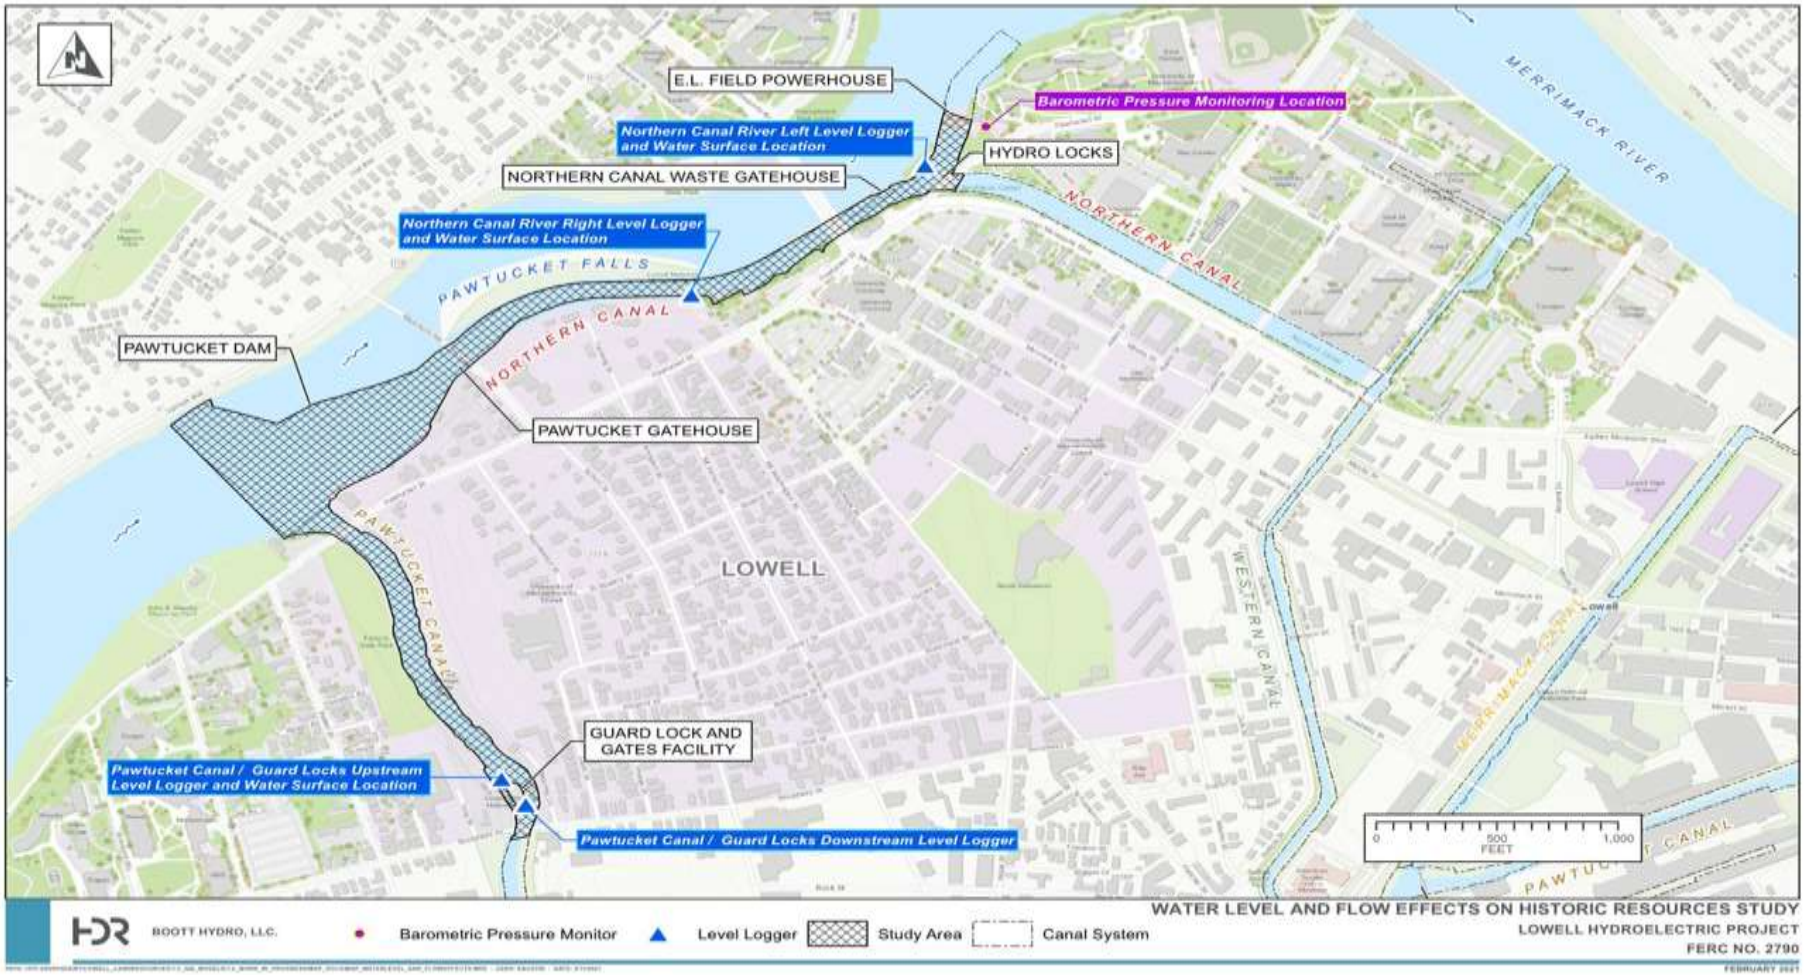
At the time of installation, and during each data download event, the vertical distance from the water surface (above each level logger) was measured to a temporary local fixed reference point ("local benchmark") which was used to correct any relative vertical change in level logger placement after data download events which occurred approximately monthly during the study period. Each local benchmark was then surveyed using an EOS Gold Global Positioning System with Real-Time Kinematic and sub-centimeter accuracy. Accordingly, the collected data was converted to an elevation which represents the elevation of the water surface at each location. This elevational data was then converted to the NGVD 29 using the National Oceanic and Atmospheric Administration's Vertical Datum Transformation tool (VDatum) to match the existing elevation data in Boott's Supervisory Control and Data Acquisition System (SCADA).

Level loggers were installed at 4 locations within the study area. Level logger locations are consistent with the areas of interest as identified by the NPS, with exact location within each area of interest determined by channel geometry, hydraulic conditions and field conditions.

A primary and backup level logger was installed at each location and recorded relative water depths at 15-minute intervals over the study period which extended from March 10 to September 23, 2020. Additionally, a single atmospheric logger was deployed within the study area at the E.L. Field Powerhouse to allow for calibration and barometric pressure correction. A total of nine instruments were deployed (eight in-water, and one atmospheric). The level logger locations include one location on the Northern Canal on river left (RL) adjacent to the Emergency Spillway Gate, a second location on the Northern Canal on river right (RR), near the intersection of Fletcher and Pawtucket Streets, and two

locations (one upstream and one downstream) on the Pawtucket Canal at the Guard Lock Gate Complex and are depicted in Figure 4-1 below.

Figure 4-1. Water Level and Flow Effects on Historic Resources Study Area



4.4 Project Operations Review

Boott reviewed Project operational data including headpond elevation, forebay elevation, Project operations, and Merrimack River flows. Boott then compared the results of these reviews to the water surface elevations recorded during the study periods, the elevations of historic structures and the existing conditions of those structures to determine the potential effect (if any) to the current conditions and expected conditions of such structures.

4.5 Visual Engineering Assessment of the Great River Wall

Boott conducted a review of prior structural engineering assessments of the Great River Wall, including review of available engineering and architectural drawings, maintenance records, photos and structural modifications. The results of this document review are summarized in Appendix B and filed with this report as Critical Energy Infrastructure Information (CEII).

On October 5-6, 2021, Boott visually assessed the existing conditions of the Great River Wall. The goal of this visit was to observe and photograph the existing condition of the Great River Wall that could be visually observed from the safety of available access points. The results of this document review are summarized in Appendix C and filed with this report as Critical Energy Infrastructure Information (CEII).

4.6 Analysis of Potential Project Related Effects

Boott analyzed the data collected in each of the five sections above to determine if and when Project operation flows into the canal system may have resulted in water levels reaching elevations to inundate wooden structural elements, or if periods of low flows may have caused damage to historic infrastructure.

5 Study Results

5.1 Documentation Review of Existing Conditions

Pursuant to the approved study plan, Boott reviewed several source documents to better understand the elevations of structures potentially effected by fluctuating water levels in the Northern and Upper Pawtucket Canals. The following list includes those documents reviewed[3].

- Proprietors Canal System Book of Facts.

[3] Some documents referenced in this study report and included in this list are considered Critical Energy Infrastructure Information (CEII) by the FERC and are not for public distribution and are also not included in Appendix A of this study report.

- Supporting Technical Information Document – Guard Locks and Gates Facility (NATDAM No. MA 00834) Lowell Hydroelectric Project FERC No. 2790-MA Lowell, Massachusetts. 2015.
- Dam Safety Inspection Report for the Lowell Hydroelectric Project FERC No. 02790-MA.
- U. S. Department of Interior (USDOI) comments on the PAD, comments on SD1, and study requests dated August 14, 2018 regarding Boott Hydropower, LLC, Lowell Hydropower Project (FERC No. 2790-072), Merrimack River, Middlesex County, MA, and Hillsborough County, NH.
- USDOI Request for Information Response February 3, 2021 regarding requested Information in response to Central Rivers Power letter dated 01/20/2021, Lowell Hydropower Project (FERC No. 2790-072), Water Level and Flow Effects on Historic Resources Study.
- Lowell Hydroelectric Project (FERC No. 2790) Exhibit E and F Drawings obtained from the circa 1980 Application for License for Major Project.
- Lowell Heritage State Park Drawings for the Lowell Canal System circa 1983. Department of Environmental Management division of Forests and Parks.
- E.L. Field Powerhouse operational data including but not limited to project generation, project flow, headpond elevations, project inflow, project outflow, fishway operations, etc.
- Historic American Engineering Record, National Park Service, Louis R. Scurci, 1974.
- Pawtucket Gatehouse Facility Ex Condition Photographs, 2020
- Northern Canal – New Lock Gates: Plans, Elevation Details, and Hardware. August 1984.
- Francis Guard Gate Sluice Gatehouse Ex Condition Photographs, 2020
- LNHP, Rehabilitate Northern Canal Waste Gatehouse. 100% Construction Documents June 28, 2018
- LNHP, Rehabilitate Northern Canal Waste Gatehouse. LOWE-225866 Project Specifications Construction Documents. NPS, Northeast Region 100% Submission June 28, 2018
- Project Scoping Report. Task Order #P17PD03094; Contract #P15PC00036; PMIS #225866 Northern Canal Waste Gatehouse. November 13, 2017.
- Rehabilitate Northern Canal Waste Gatehouse. LNHP, Lowell, MA Estimate Class A February 2, 2018.

Boott reviewed the above listed data to identify elevations, conditions, and other relevant information regarding historical structures that may be potentially affected by project operations related to water level fluctuations in the project headpond, Northern Canal and Upper Pawtucket Canal. While many of these documents contain relevant information

related to the conditions of relevant historic structures, there are few, if any details on the elevations of these structures in relation to water level fluctuation.

5.2 Canal Water Level Monitoring

As noted above, the objective of this study was to analyze the potential effects of water level fluctuations from project operations in the Northern Canal and the Upper Pawtucket Canal on historic structures with a focus on the Pawtucket Gatehouse, the Northern Canal Waste Gatehouse, the Guard Lock and Gatehouse Complex and the Great Wall.

The level loggers and associated elevation data captured a sufficient range of operational conditions (including spring freshet flows and summer low flows) over the course of the deployment period, to show a typical period of water surface elevation at each of the locations listed above. Additionally, the water surface elevations of the Project headpond and the Project forebay over the available period of record (1995 through 2010) allowed Boott to analyze the potential effects of water level fluctuations on historic structures in and along these canals.

5.2.1 E.L. Field Headpond/Northern Canal Lock

Water surface elevations within the Project headpond at the Northern Canal Lock during the study period (March 10 – September 29, 2020) range from a minimum of 91.76 ft to a maximum of 92.30 ft for a range of 0.54 ft (Figure 5-1).

Figure 5-2 shows the estimated elevations of the top and bottom sill of the Pawtucket Gatehouse Lock Gate relative to the water level of the Project headpond.

Figure 5-1. Project Headpond Water Surface Elevation During 2020 Monitoring Period

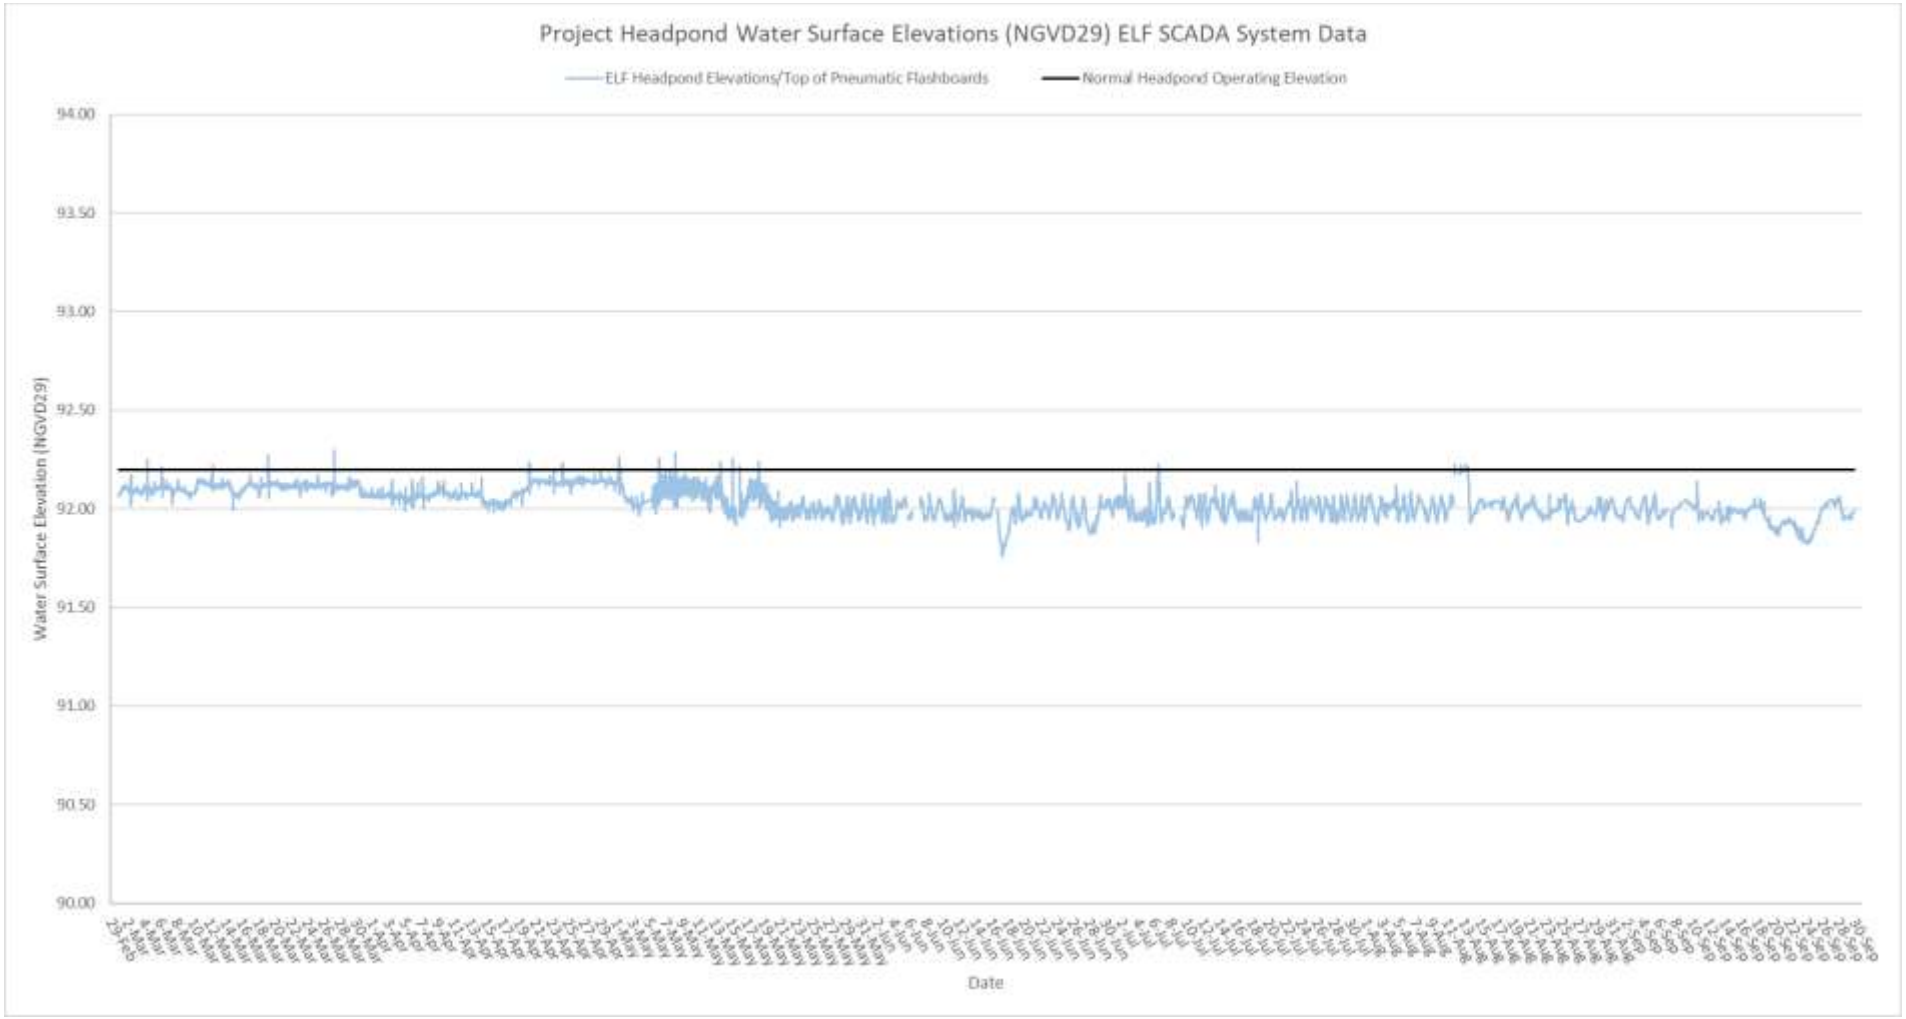


Figure 5-2. Project Headpond Water Surface Elevation During 2020 Monitoring Period Relative to Top and Bottom Sills of the Northern Canal Lock Gate

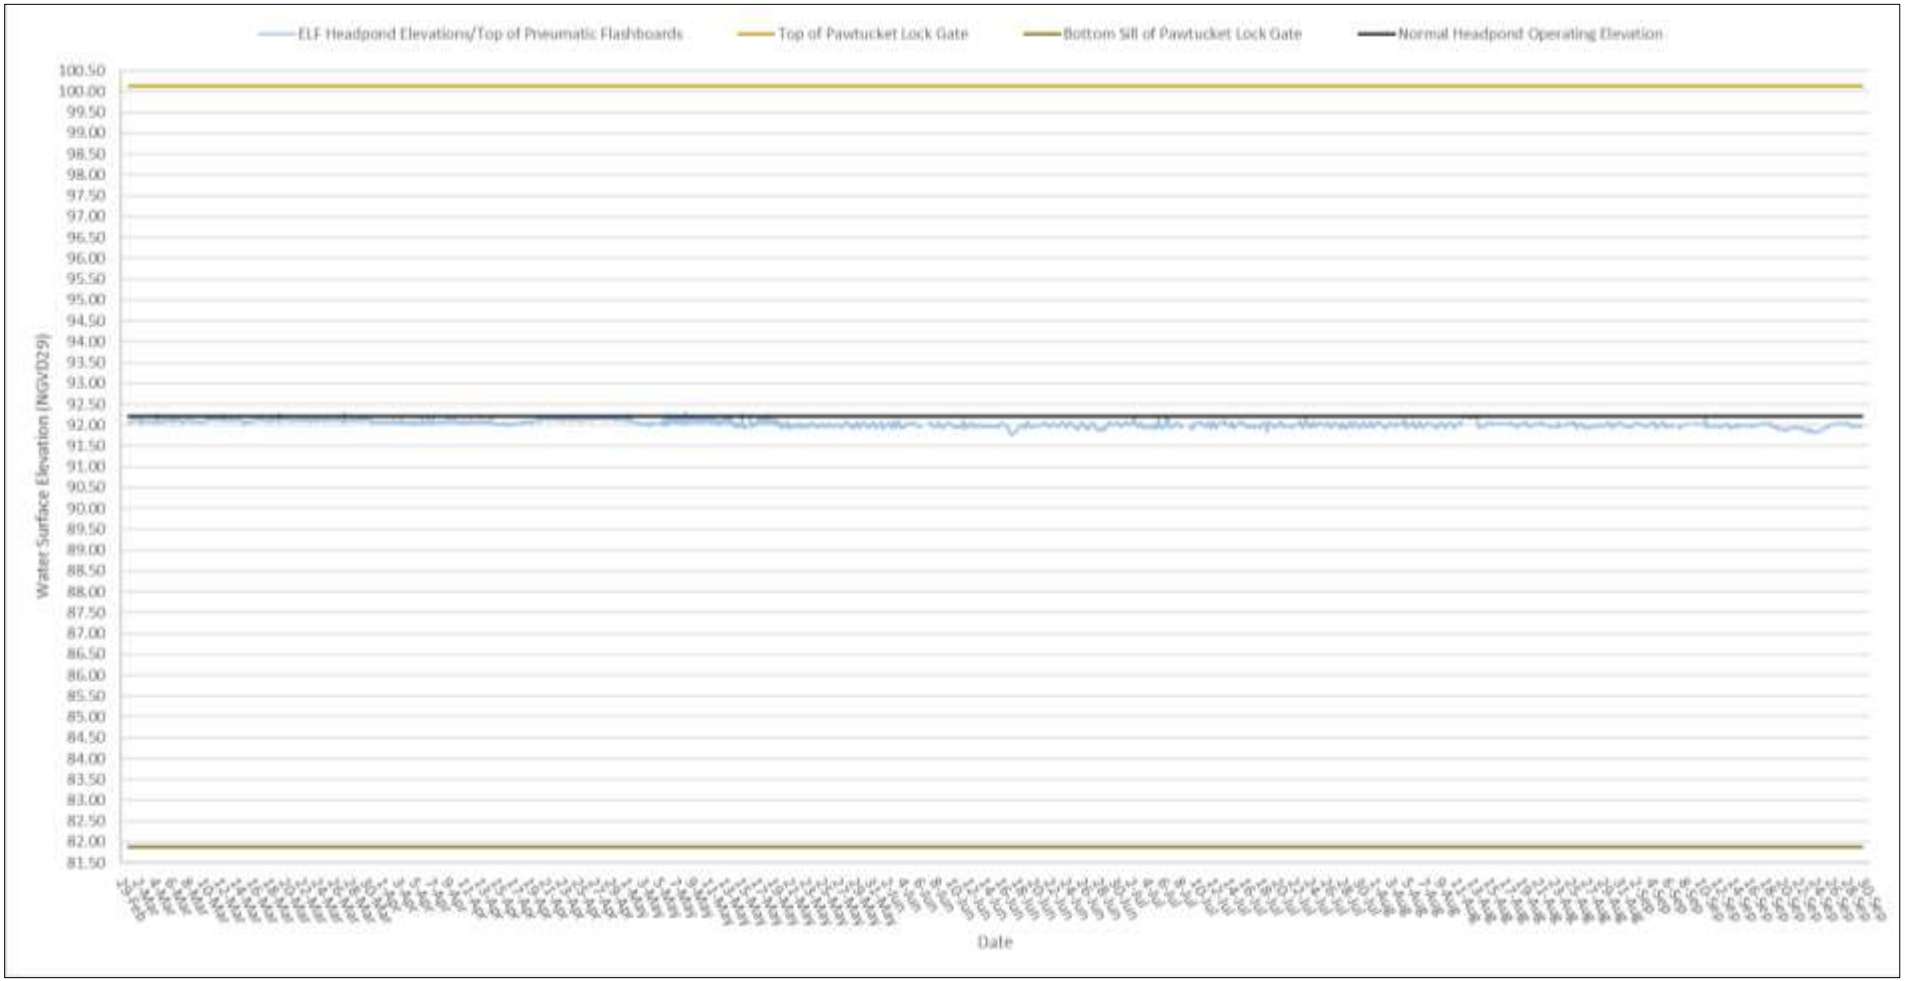

5.2.2 Northern Canal

Water surface elevations within the Northern Canal collected during the study period ranged from a minimum of 85.30 ft to a maximum of 91.64 ft (Figure 5-3) with a range of 6.34 ft at the Northern Canal River Left (RL) location near the Emergency Surge Gate and from a minimum of 85.71 ft to a maximum of 92.14 ft (Figure 5-4) for a range of 6.43 ft at the Northern Canal River Right (RR) location, near the canal's mid-point between the Pawtucket Gatehouse and the E.L. Field powerhouse.

Based on the level logger data collected in the Northern Canal at the RL location, water surface elevations within the Northern Canal reached elevations greater than 91.5 ft (the normal maximum operating elevation of the Northern Canal) on one occasion during the monitoring period. Beginning on August 11 at approximately 9:45 PM through August 13 at approximately 3:45 p.m. the water surface elevation in the Northern Canal was greater than 91.5 ft reaching a maximum elevation of 91.64 ft (Figure 5-3).

Based on the level logger data collected in the Northern Canal at the RR location, water surface elevations within the Northern Canal reached elevations greater than 91.5 ft (the normal maximum operating elevation of the Northern Canal) on three occasions. On March 19 at approximately 9:00 a.m. the water surface reached a maximum elevation of 91.52 ft for less than 15 minutes. On May 15 at the RR location, the water surface elevation within the Northern Canal rose above 91.5 ft for approximately 10 hours and reached a maximum elevation of 91.62 ft. Beginning on August 11 at approximately 9:45 p.m. through August 13 at approximately 3:45 p.m. the water surface elevation in the Northern Canal at the RR location was greater than 91.5 ft reaching a maximum elevation of 91.64 ft (Figure 5-4).

Figure 5-3. Northern Canal River Left Location - Water Surface Elevation During 2020 Monitoring Period

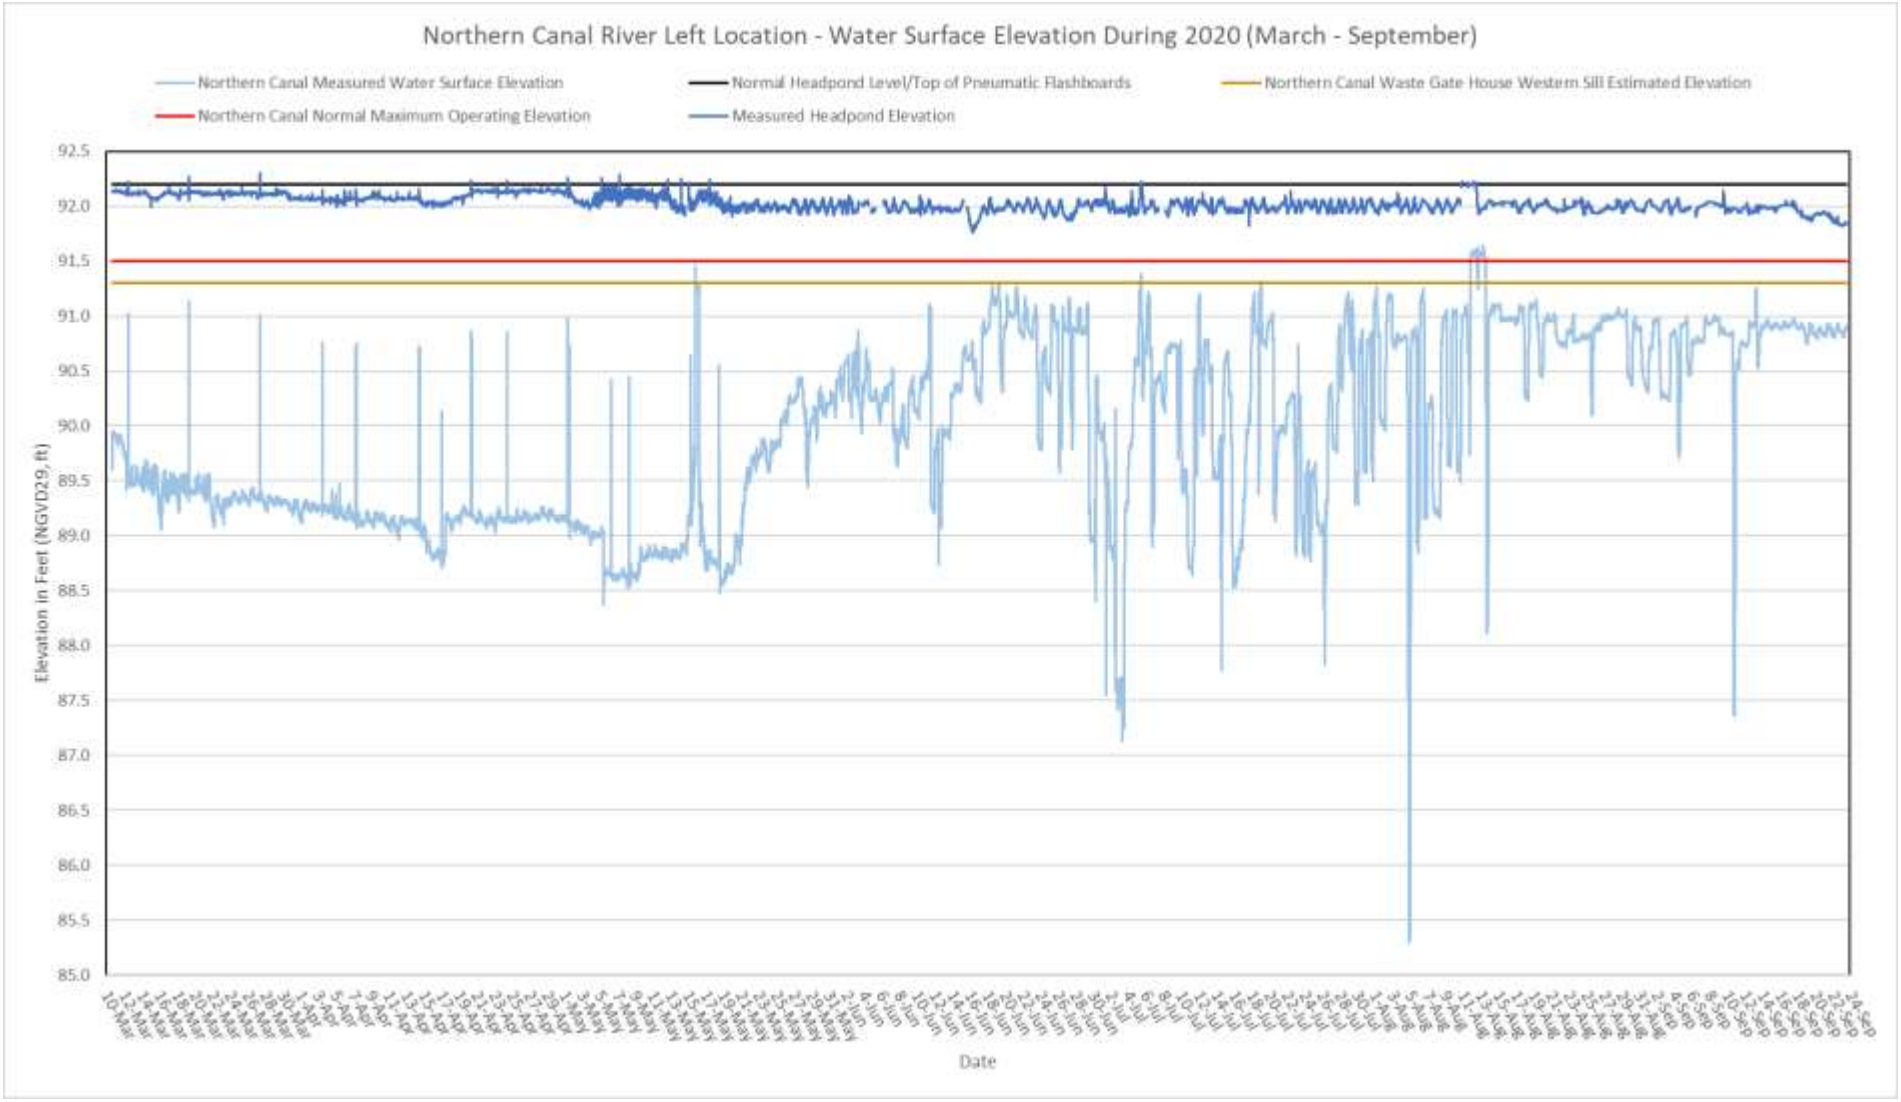

Figure 5-4. Northern Canal River Right Location - Water Surface Elevation During 2020 Monitoring Period. Pawtucket Canal

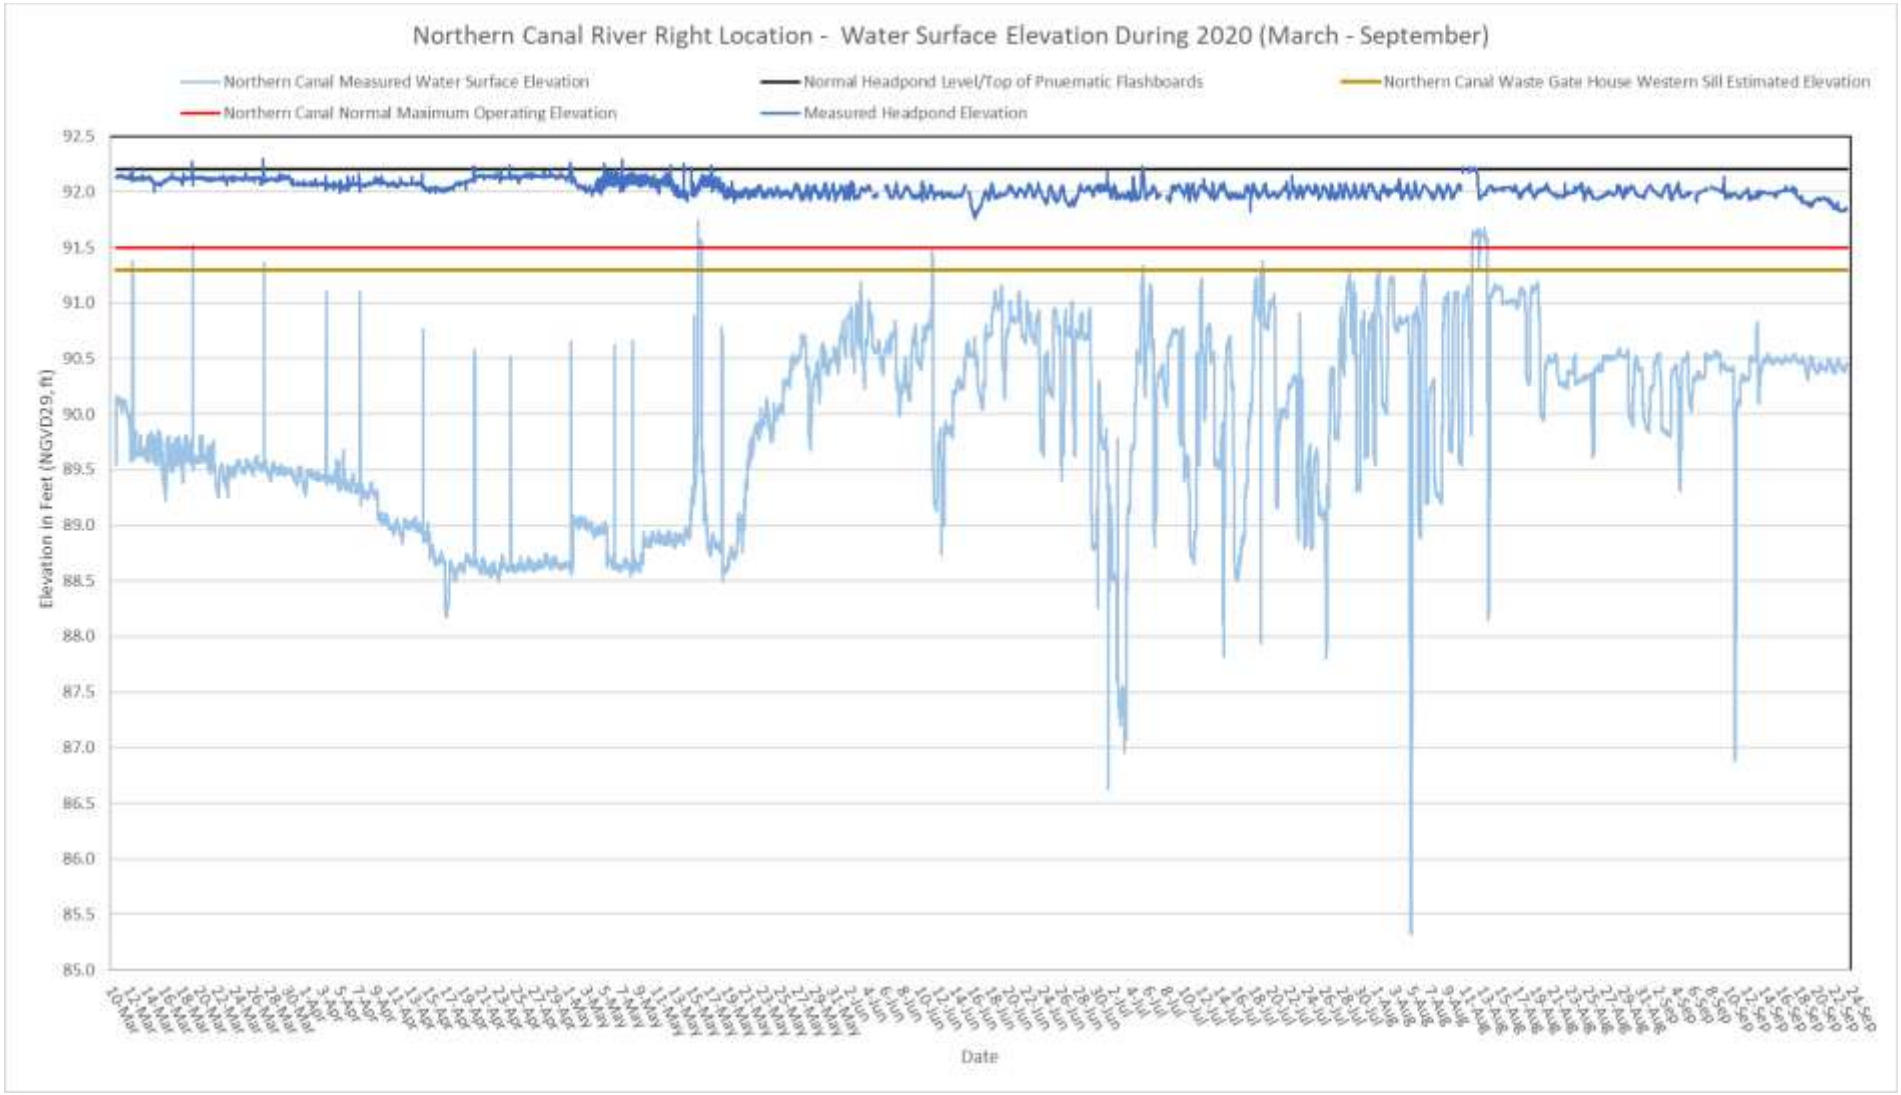

5.2.3 Upper Pawtucket Canal

Water surface elevations within the Upper Pawtucket Canal during the study period ranged from a minimum of 91.69 ft to a maximum of 92.35 ft (Figure 5-5) for a maximum range of 0.66 ft, and are consistent with the impoundment level data. Within the Lower Pawtucket Canal levels ranged from a minimum of 79.53 ft to a maximum of 86.21 ft (Figure 5-6) for a range of 6.68 ft. Water surface elevation data downstream of the Guard Lock Gate Complex were not collected following the June 12 download event due to loss of the downstream level loggers (Lower Pawtucket Canal). These loggers were not recovered nor replaced.

On one occasion during the study period, the water surface elevation within the Upper Pawtucket Canal reached an elevation greater than 92.2 ft (the normal operating elevation of the Project headpond). This event occurred from March 27 at approximately 11:30 a.m. and lasted for less than 15 minutes, reaching a maximum elevation of 92.29 ft.

The Lower Pawtucket Canal was drawn down approximately 6.5 ft from April 2 through April 7, 2020 to facilitate bridge reconstruction in downtown Lowell, but generally remained between elevations 88.25 ft and 89.47 ft, a range of 1.22 ft during the remaining study period.

Figure 5-5. 2020 Upper Pawtucket Canal Water Surface Elevation (March 10 - September 24)

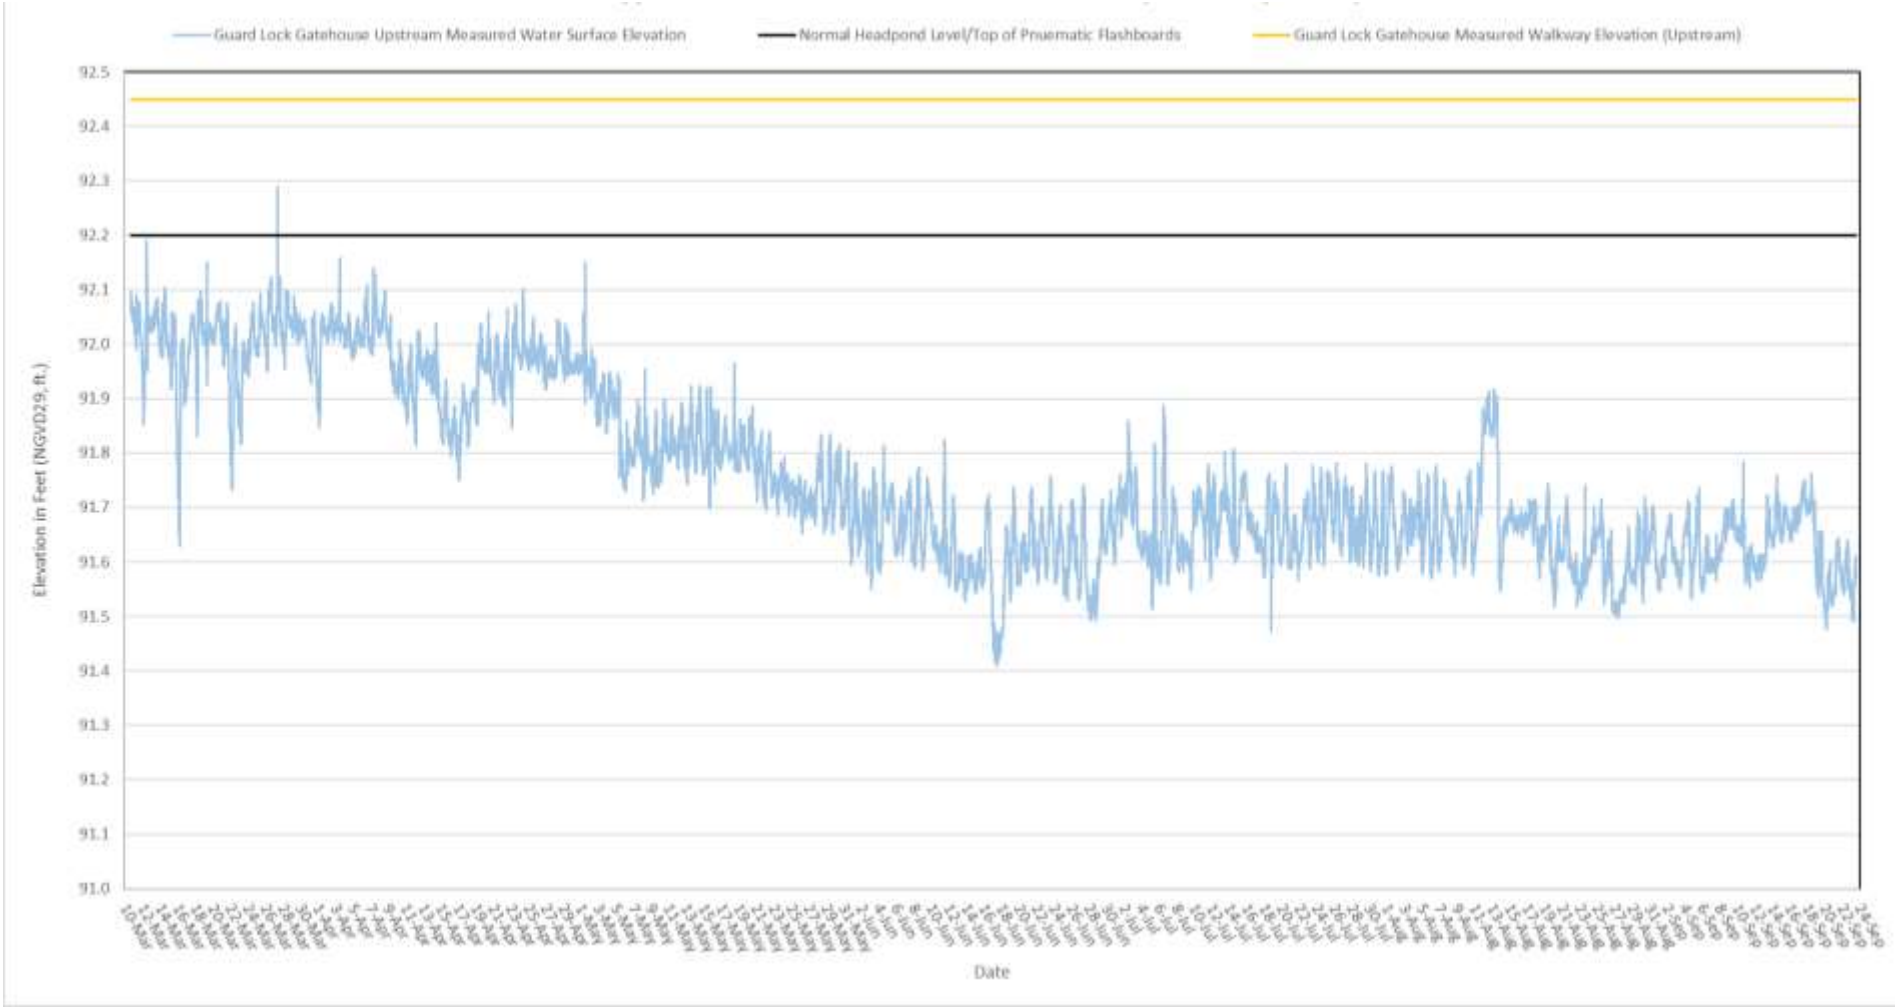

Figure 5-6. 2020 Lower Pawtucket Canal Water Surface Elevation (March 10 – June 11)

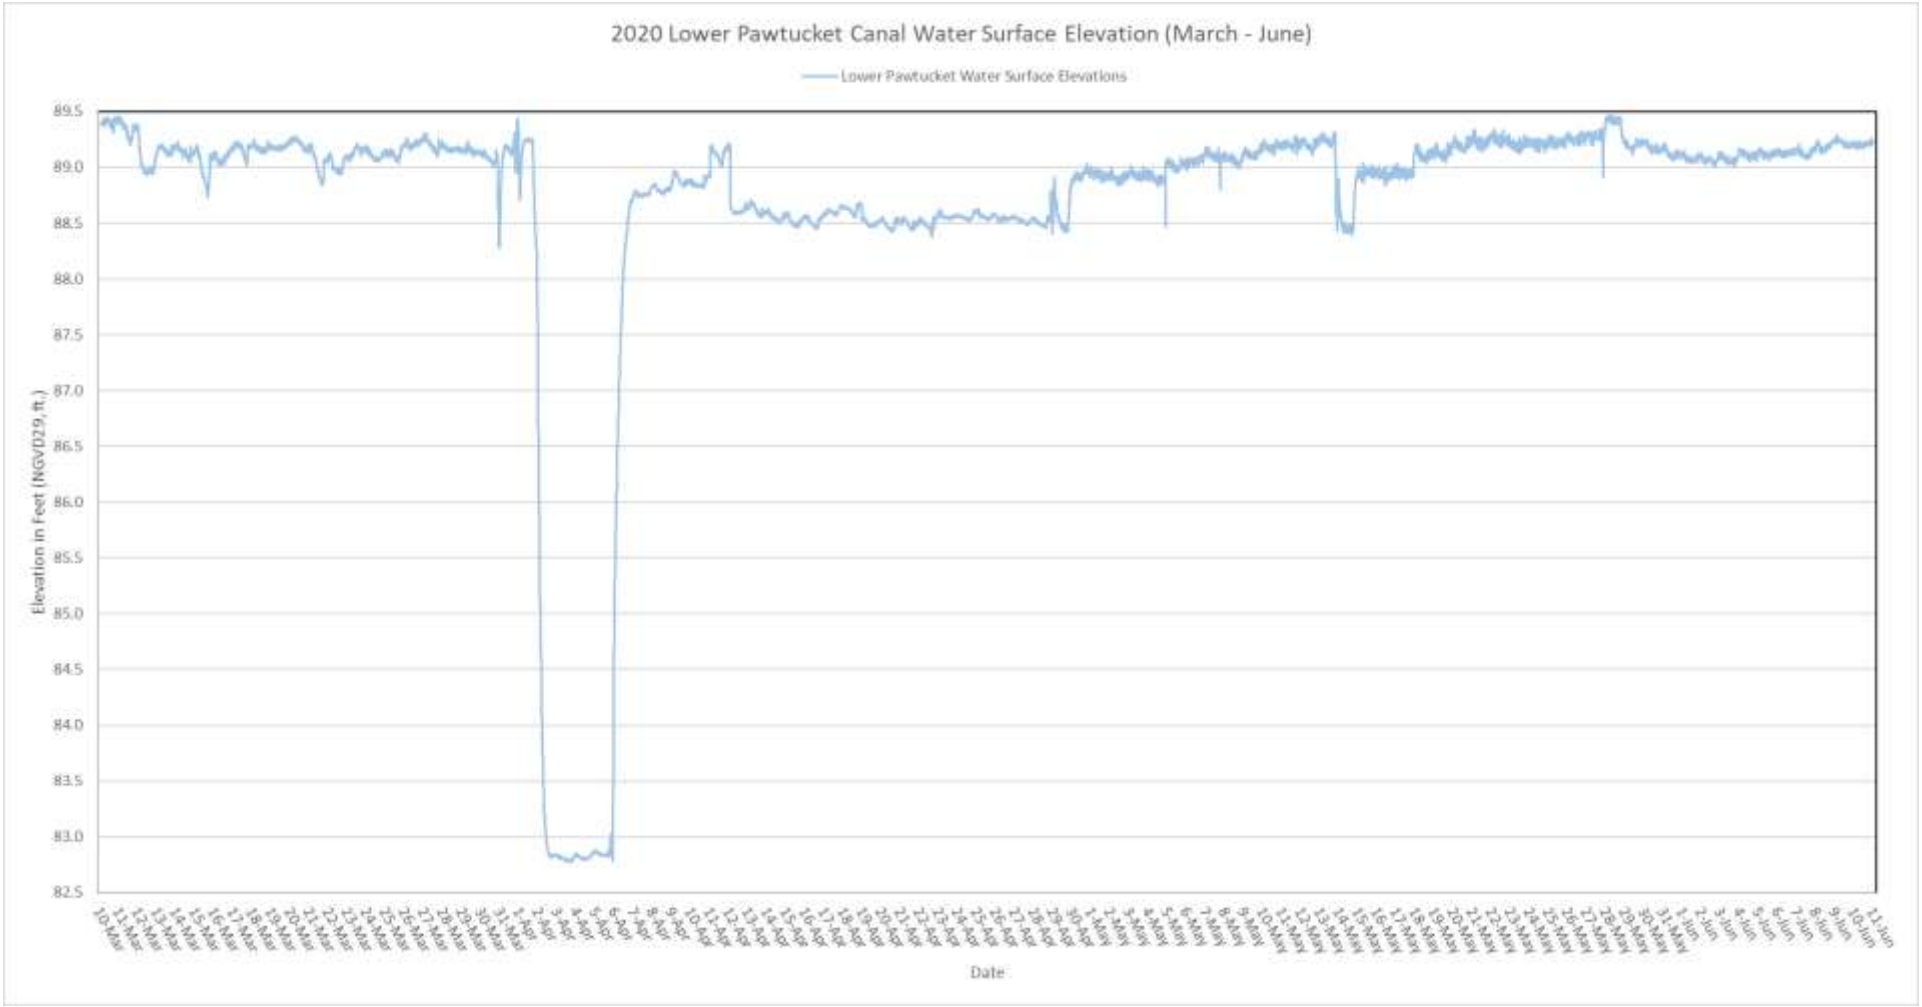
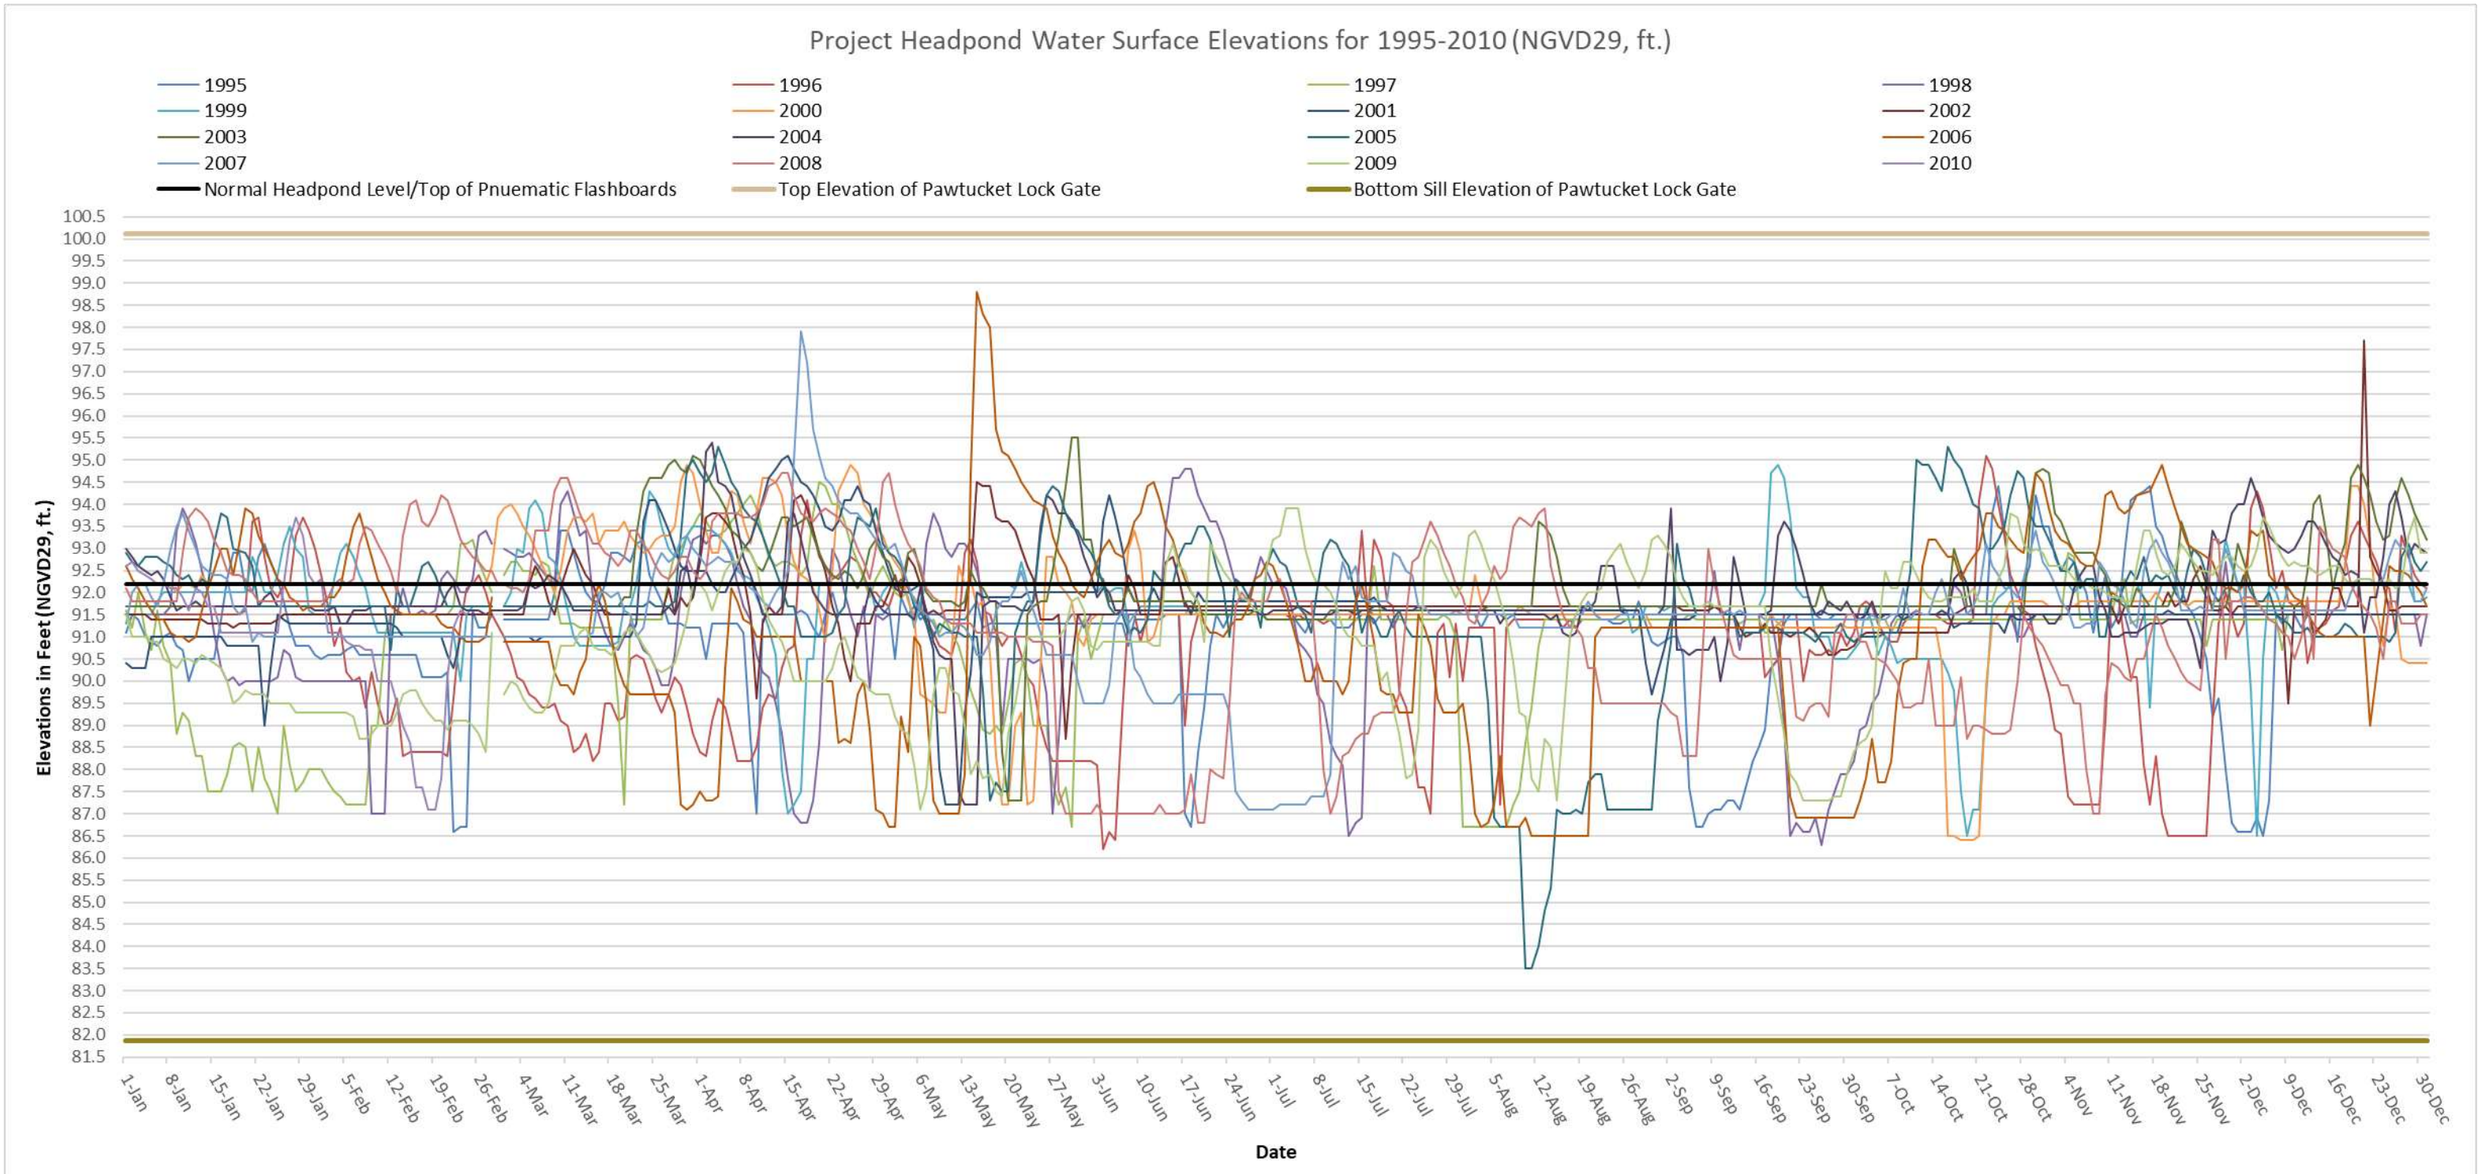


5.3 Project Operations Review

Boott has reviewed the operational data for the Pawtucket Dam headpond elevations and the E.L. Field Powerhouse forebay elevations for the available period of record (January 1995 through December 2010 (Figure 5-7 and Figure 5-8). These data are from the period when 5- foot- high wooden flashboards were deployed on the spillway crest, prior to the construction of the present pneumatic crest gate system. The data demonstrate that with the wooden flashboards, headpond levels were highly variable, due in large part to the Licensee's inability to maintain normal pond level when the flashboards were partially damaged or failed. Repair and replacement of the failed flashboards required a 5-foot drawdown of the project impoundment, typically for 2 days, to enable safe working conditions on the dam crest. In contrast, the pneumatic crest gate system maintains a steady impoundment level by automatically adjusting the height of the crest gate panels in response to increasing flows (Figure 5-1 and Figure 5-2). As flows recede the crest gates are automatically raised, thereby eliminating any need for impoundment drawdowns for flashboard repairs. With the original flashboards in place, headpond elevations were driven by the type of water year (wet, normal, dry) and were much more variable, although typical for a riverine environment. Figure 5-7 shows that during most normal years the headpond is maintained at or near crest elevation for a large portion of the year. Exceptions occur during seasonal spring freshet (mid-March to mid-April), during the fall rainy season (mid-October to early December) and during the occasional anomalous event.

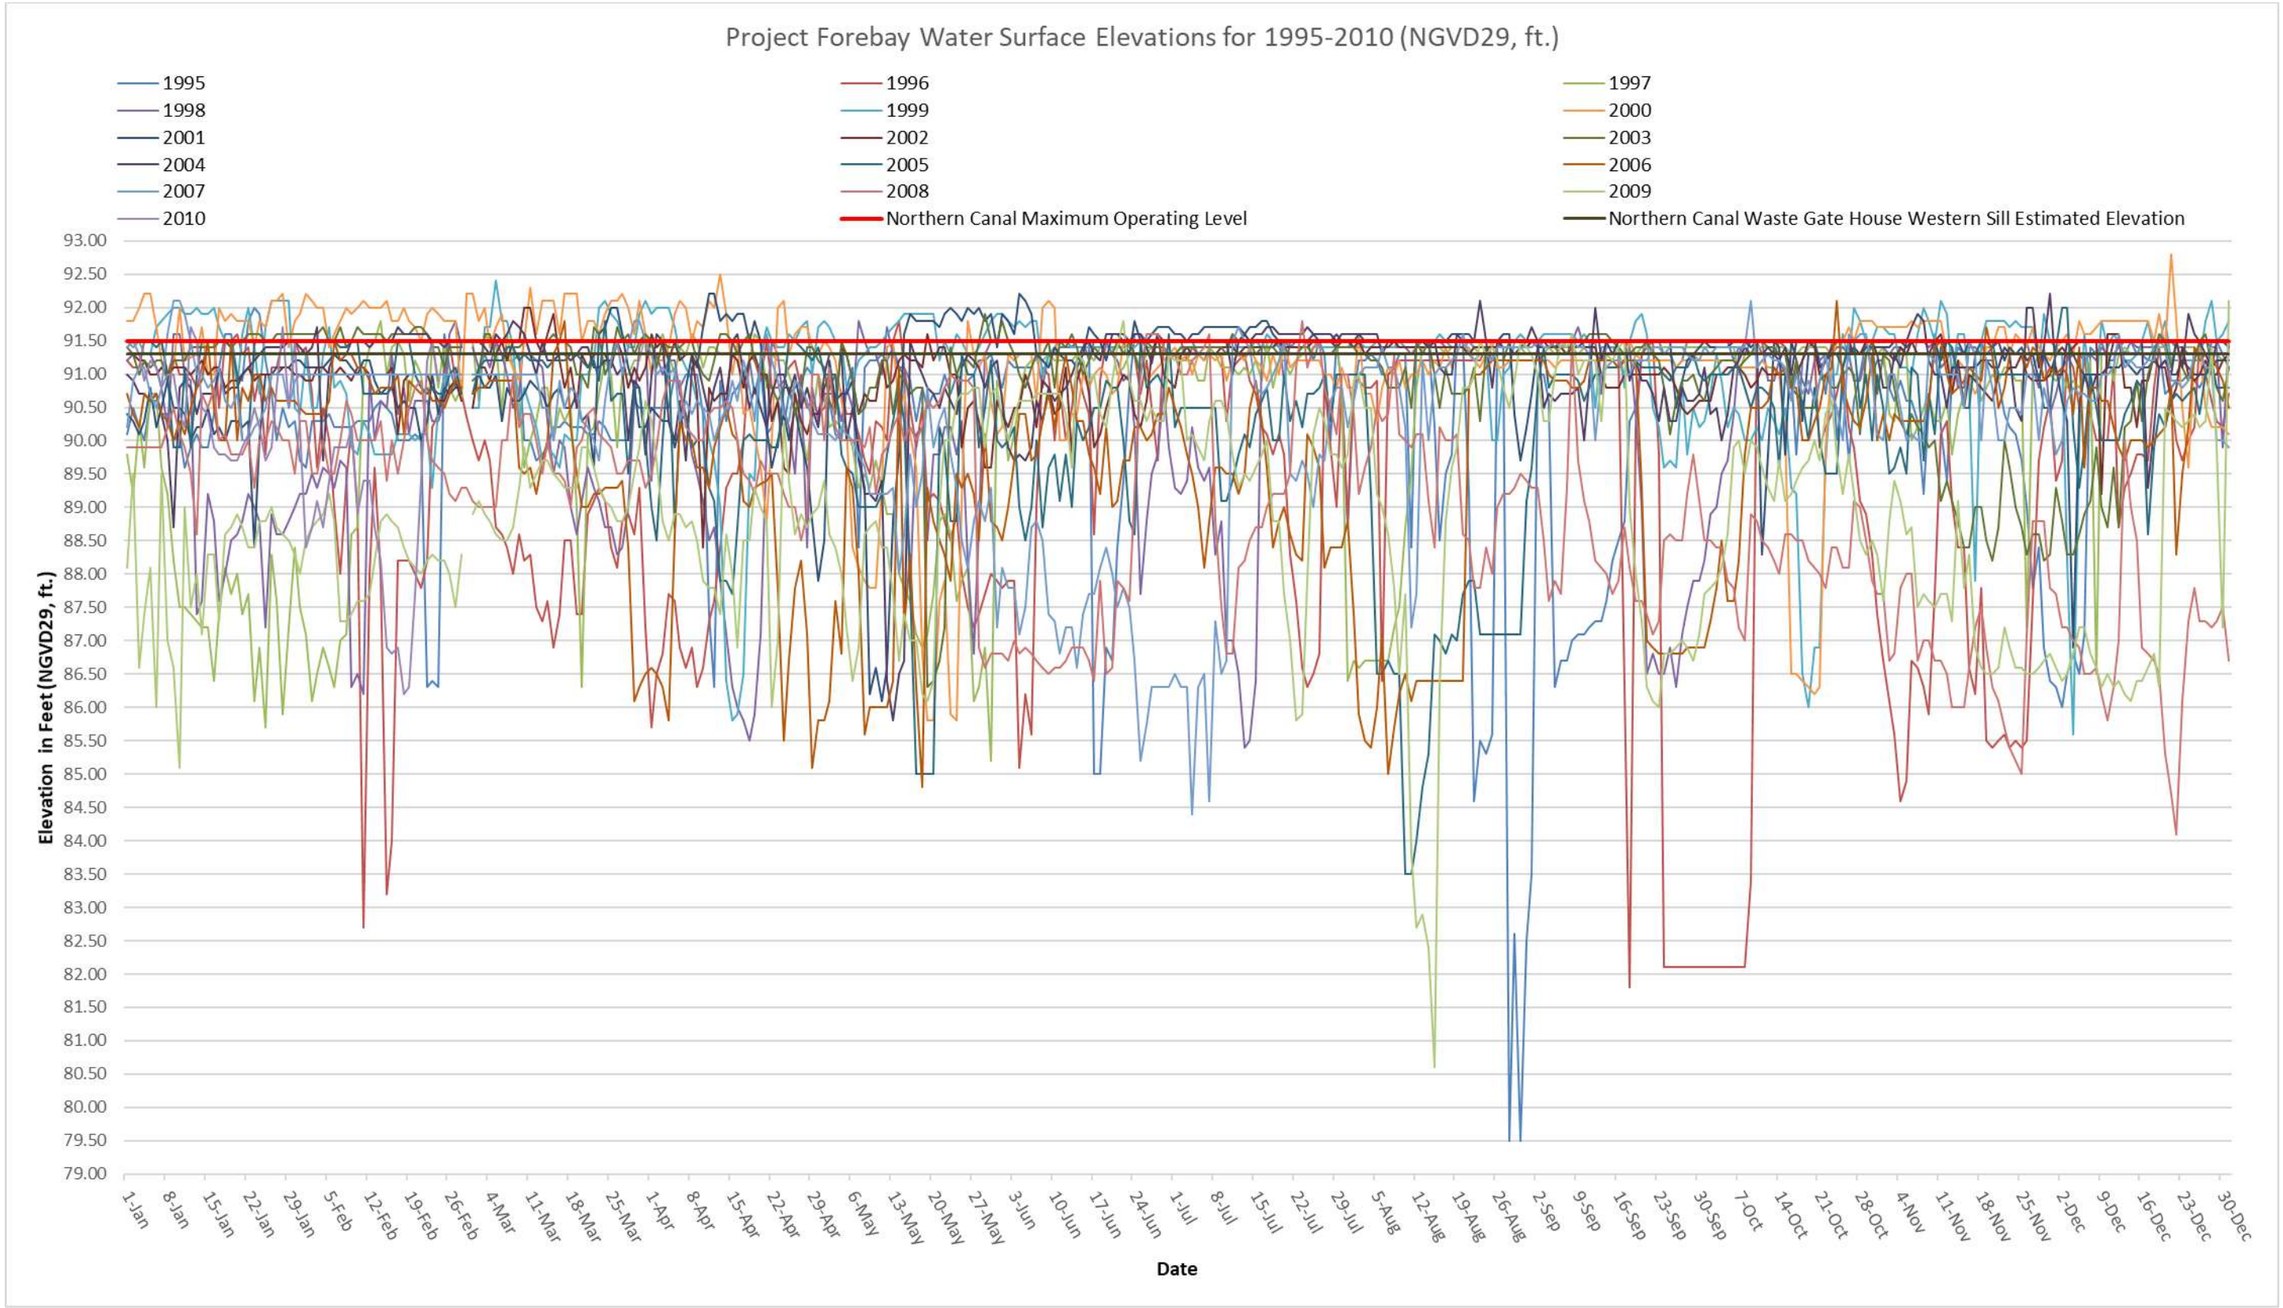
Notable in both the current data set with the crest gate (Figure 5-3 and Figure 5-4) and the historic data set with flashboards (Figure 5-3 and Figure 5-4) is that there is often a large water level differential across the Pawtucket Gatehouse, often reaching 3 or more feet. Normally, this differential would be only 0.7 ft, i.e., 92.2 ft normal pond elevation versus 91.5 ft maximum Northern Canal elevation. However larger differentials may occur, typically due to debris accumulation on the upstream side of the gatehouse, which restricts flow through the headgates (Photo 5-1). Large differentials are most common during the late winter and spring, when increased river flows bring large amounts of river debris down the river. This is a factor which has not been changed by the replacement of the original wooden flashboards with the pneumatic crest gates. Boott has not analyzed the data sufficiently to determine whether there is any difference in differentials between the pre- and post- crest gate data.

Figure 5-7. Merrimack River – Pawtucket Dam Headpond Elevations for Period of Record (1995-2010)[4]



[4] Period of Record Data 1995-2010 was recorded with 5-foot high wooden flash boards in operation and prior to the installation of the automated pneumatic flashboards along the crest of the Pawtucket Dam.

Figure 5-8. Northern Canal E.L. Field Powerhouse Forebay Elevations for Period of Record (1995-2010)



5.4 Visual Assessment of the Great River Wall

The review of prior structural engineering assessments of the Great River Wall and the visual observation are designated as CEII and as such are not available for public distribution.

5.5 Analysis of Potential Project Related Effects

Pursuant to the RSP, Boott analyzed the information obtained from sections 5.1 through 5.4 above, to assess the potential for project related effects to cause adverse impacts to the historical structures along the Northern and Upper Pawtucket Canals. Factors that may have the potential to effect historic resources can vary according to several factors including but not limited to Project operations, the magnitude and duration of natural high and low flow events, river debris and trash accumulation, natural decay, Project related maintenance, and non-Project related maintenance by other entities.

5.5.1 Northern Canal Lock and Pawtucket Gatehouse

The Northern Canal Lock and the Pawtucket Gatehouse (Photo 5-1) is located at the southern abutment of the Pawtucket Dam and controls flow into the Northern Canal. It is principally constructed of dressed masonry with concrete over lintels and contains ten 8-foot-wide by 15-foot-high, motor-operated, timber sliding gates which feed the Northern Canal. Another small intake opening feeds a presently unused wheel, which formerly powered the gate mechanisms through a line shaft. The structure's water passages are nearly 80 ft in length. A small navigation lock is located at the southerly end of the Pawtucket Gatehouse (Photo 5-2) (Boott 2017).

The Project is operated in a run of river mode (ROR) where outflow approximates inflow, generally maintaining the Project headpond at or near elevation 92.2 ft (see Figures 5-1 through 5-4). Under normal operations, Boott operates the Project to prioritize the E.L. Field Powerhouse generating units. When flows exceed the 6,600 cfs combined hydraulic capacity of the E.L. Field generating units, it has been Boott's practice to divert up to 2,000 cfs to the downtown canal units when they are operable. Flows higher than 8,600 cfs (the combined capacity of the E.L. Field Powerhouse and the canal units) are spilled over the Pawtucket Dam spillway and into the Project's bypass reach. The pneumatic crest gate system has a control system which maintains a constant upstream water level during increasing flows, by automatically lowering the crest gate panels as the spillway flow increases.

The concrete and masonry gatehouse show normal wear from exposure to the natural river conditions and Project water level fluctuation. Based on a review of existing documentation and consultation with the NPS, Boott did not identify potential Project-related effects on the gatehouse.

Photo 5-1. Northern Canal Lock and Pawtucket Gatehouse.

Photo 5-2. Pawtucket Gatehouse at Northern Canal Gate entrance (prior to 2018 gate damage).

Potential Project-related effects have been documented at the Northern Canal lock structure. The lock structure is controlled by a set of timber miter gates, with one set of gates at the upstream entrance/exit and a second set at the downstream entrance/exit. The gates are subject to routine water level fluctuations (see Figure 5-1 through Figure 5-4) that can deteriorate wooden and metal elements. While the magnitude of fluctuation in the Project's headpond has been significantly reduced by the implementation of the pneumatic crest gates, the gates are subject to routine seasonal high flow events. Portions of the gates are also continuously submerged, which contributes to natural deterioration of wooden and metal elements over time. Photo 5-3 shows the normal water level that is maintained approximately midway on the gate height, and Photo 5-4 shows the deterioration of wood and metal on the removed gate normally below the water surface.

On August 26, 2018, the right (facing downstream) timber gate controlling the upstream entrance/exit to the Northern Canal lock was damaged. The damage to the gate was caused by an unusual back surge of water moving upstream through the Northern Canal,

caused by a water level transducer malfunction. Under normal operations, the existing surge gate would be automatically activated upon full shutdown of the E.L. Field units to discharge the resulting back-surge of flow into the bypass reach. In this instance, the surge gate did not open because the malfunctioning transducer at the Pawtucket Gatehouse caused the E.L. Field units to back down rapidly but did not cause the them to trip off-line. As a result, the rapid unit backdown created a water-hammer effect that surged up the Northern Canal and into the miter gates. The gates had been previously chained together at their upper corner (See Photo 5-3), which prevented the gates from opening and releasing the surge as it moved upstream, and thus causing the right gate to break. Boott has recently removed the gate from service, and it is currently under repair.

Other factors which have likely contributed to the deterioration of the miter gates include, but are not limited to, high flows in the Merrimack River and natural deterioration of the submerged portions of the wooden gate structure, neither of which are attributable to Project operations.

Photo 5-3. Damage to the Northern Canal Lock Timber Gate.

Photo 5-4. Photo of wear of submerged portion of the Northern Canal Gate removed for repair.

5.5.2 Northern Canal Waste Gatehouse

The Northern Canal Waste Gatehouse is a single-story, heavy-timber-framed building, built circa 1872 atop the Great River Wall which houses gate operators for four canal release gates (Photo 5-5). Based on consultation with the NPS, Boott identified potential Project-related effects on certain wooden structural elements of the Northern Canal Waste Gatehouse. The wooden sills of the gatehouse have experienced deterioration. Boott reviewed Northern Canal water level data recorded in 2020 to determine if Northern Canal water levels could be a contributing factor to the deterioration of the sill.

Photo 5-5. Northern Canal Waste Gatehouse atop the Northern Canal.

As shown in Figure 5-3 and Figure 5-4, the Northern Canal Waste Gatehouse has wooden sill which overhangs the Northern Canal, with a bottom elevation of approximately 91.3 ft NGVD29. The normal maximum operating elevation of the Northern Canal is 91.5 ft. Figure 5-3 and Figure 5-4 show that the canal water surface elevations for the study period occasionally exceeded the bottom sill elevation, thereby inundating the heavy timber bottom sill on the south side of the structure (Photo 5-6). The Northern sill of the Waste Gatehouse has also deteriorated, due to natural exposure to the nearby river and atmospheric conditions, as well as its proximity to the spillway immediately to the east. It is possible that splashing water from the adjacent spillway may have contributed to the deterioration of the eastern third of the northern sill timber. Repeated inundation and drying of the timber sill can be a contributing factor to deterioration. Other factors, including the age of the wooden timbers, general maintenance, weathering, and atmospheric conditions are also likely to have contributed to the deterioration of the southern sill, and the eastern portion of the northern sill. The age of the sills is not known, i.e., it is not known if the existing sills are the original timbers from the 1872 construction of the gatehouse.

Photo 5-6. Northern Canal Waste Gatehouse underlying timber sill.

5.5.3 Guard Lock and Gates Facility

The Upper Pawtucket Canal branches off the Merrimack River a few hundred feet upstream of the Pawtucket Dam and feeds water into the downtown canal system via the Guard Lock and Gates Facility ("Guard Locks"). The facility consists of the following structures: 1) the Guard Gatehouse which houses 5 sluice gates to convey flow to the Lower Pawtucket Canal; 2) a 24 ft wide granite masonry Lock Canal with two pairs of wooden lock gates; 3) the timber and wood framed Lock House located above the upstream lock gate; 4) the Francis Gatehouse (or Great Gatehouse) timber and wood framed structure over the Lock Canal which houses the 25' high x 25' wide Francis (or Great) Gate. The Guard Gatehouse is separated from the Lock Canal and associated Lock House and Francis Gatehouse by an island with walls of granite, ledge, or concrete (Photo 5-7).

In its consultation comments, the NPS identified potential Project-related effects on the Guard Lock and Gates Facility. Specific issues identified by the NPS included damage to the upstream side of the gatehouse (including the upstream wooden walkway), erosion of the steps leading to the gatehouse, and damage to the entry door on the east side of the Gate House. Boott reviewed the available information regarding the condition of the Guard Locks Facility with respect to the potential impacts identified by the NPS.

Photo 5-7. 1976 - Guard Lock and Gates Facility viewed from upstream. The Guard Gatehouse is on the left and the Lock Canal and Lock House are on the right.

Photo 5-8. 2019 - Guard Lock and Gate Facility.

Water levels in the Pawtucket Canal upstream of the Guard Locks complex are essentially the same as the project impoundment and remained below the normal headpond level of 92.2 ft NGVD29 throughout the study period except for one occasion. On March 27, 2020 between 11:30 a.m. and 12:00 p.m. the water level in the Pawtucket Canal upstream of the Guard Locks reached 92.29 ft. Figure 5-5 shows the water surface elevation during the study period and the estimated elevation of the Guard Gatehouse walkway (**Error! Reference source not found.**).

Water levels in the Upper Pawtucket Canal remained below the walkway at the base of the Guard Lock Gatehouse for the entire study (Figure 5-5 and Photo 5-8). The elevation of the walkway (92.45 ft), the clapboard siding (92.45 ft), and the bottom of the mid-level windows (94.08 ft) are all above the normal water level of the Upper Pawtucket Canal (Figure 5-5). Under normal operating conditions, these features are rarely inundated. However, high flow events that are beyond Boott's control can cause water levels to exceed normal operating conditions and may inundate the walkway, clapboard siding, and mid-level windows. As described above, the pneumatic crest gate control system maintains a constant upstream impoundment elevation under elevated flow conditions by automatically adjusting the height of the crest gate panels. The crest gates would be fully lowered at river flows of approximately 35,000 cfs, above which the impoundment and Upper Pawtucket Canal level would rise uncontrolled. Thus, river flows in excess of 35,000 cfs could cause the Upper Pawtucket Canal to inundate the wooden structural elements of the gatehouse; however, these conditions are outside of the ability of the project to control the impoundment water level and therefore not attributable to Project operations.

While normal Project operating conditions do not appear to be having a significant effect on the wooden structural elements of the gatehouse, the presence of waterborne trash and debris may adversely affect the gatehouse. Trash and debris accumulate upstream from Guard Lock Gatehouse, including large logs and timbers. While the magnitude of fluctuation in the Project headpond has been significantly reduced by the implementation of the pneumatic crest gates (see Figure 5-1), the Pawtucket Canal is subject to routine seasonal high flow events, which are more likely to convey trash and debris from upriver areas. While trash and debris that accumulate upstream from the gatehouse have the potential to damage exterior wooden elements and windows under such high flow conditions, natural high flow events and waterborne trash are not related to Project operations. Boott retains a crane service to remove the trash and debris from in front of the Pawtucket Gatehouse once or twice each year.

Boott notes that the top of the steps (104.87 ft) leading to the lower level door of the Guard Gatehouse and the bottom sill of the lower level door itself (100.34 ft) are significantly above the maximum recorded Project headpond elevation for the recent period of record. According to the historic data for the period of record (1995 – 2010) the maximum elevation of the Project headpond was 98.8 ft in 2006. As such, apparent damage to these structural elements are not related to Project operations. The flood of March 20, 1936 was the only event high enough to inundate the gatehouse stairs, reaching a peak elevation of 107.3 ft at a flow of 173,000 cfs.

As is discussed in the Resources, Ownership, Boundaries, and Land Rights Study Report (Study 10), all of the structures within the Guard Lock and Gates Facility are owned by the Proprietors of Locks and Canals and the Commonwealth of Massachusetts, under the administration of the MADCR. In general, the Proprietors own the substructure of each building while the Commonwealth owns the buildings and fixtures above the foundations. Boott generally has easement rights to operate and maintain the water control equipment within each structure. NPS also retains rights to access and implement improvements such as walkway surfaces, lighting, railings, decking, benches, and landscaping. As owners, Proprietors and the Commonwealth have a right and a duty to maintain properties under their ownership, but they do not have an obligation to enhance or upgrade their properties. Similarly, an easement, such as that issued to Boott and/or NPS, allows the holder to conduct routine maintenance of the property under easement.

6 Conclusions

Wooden structural elements of the historic resources located along the Upper Pawtucket and Northern Canals appear most susceptible to damage from submergence, periodic inundation, and waterborne trash.

While the magnitude of fluctuation in the Project's headpond and the Pawtucket Canal has been significantly reduced by the implementation of the pneumatic crest gates, the Merrimack River is subject to routine seasonal high flow events that are beyond Boott's control.

High flow events can also mobilize waterborne trash and debris that have the potential to damage wooden structural elements; however, neither high flow events nor the presence of waterborne trash and debris in the Merrimack River are attributable to Project operations.

The operation of the Northern Canal has caused periodic inundation of the sill at the Northern Canal Waste Gatehouse. This inundation may be one factor in the continued deterioration of the gatehouse's southern sill. Spray from the canal spillway may also be contributing to deterioration along the eastern end of the northern sill.

While normal Project operations do not appear to be adversely affecting the Pawtucket Gatehouse Lock Structure beyond normal wear, at least one incident appears to have contributed to recorded damage to the upstream miter gate. The canal surge event that occurred in 2018 was caused by the malfunction of a water level transducer. The effect of the resulting surge was exacerbated by the practice of chaining the gates closed. This anomalous incident does not represent normal Project operations, and Boott is repairing the damage to the gate.

7 Variances from FERC-Approved Study Plan

The Water Level and Flow Effects on Historic Resources Study Report was conducted in full accordance with the methods described in the FERC-approved study plan except for the following variances:

- During meetings and consultation with the NPS after the issuance of the SPD, the stakeholders agreed to reduce the focus of this study limiting it to the Upper Pawtucket Canal from the Merrimack River downstream to the Guard Locks, and including a portion of the Project headpond in proximity to the Pawtucket Dam and the Northern Canal from the Pawtucket Dam to the E.L. Field Powerhouse.
- Because of the current COVID-19 pandemic, neither multiple-party site visits nor public meetings were conducted as part of this study. Boott consulted with the NPS to identify previous damage to historic resources within the study area and to collect additional information on the nature and extent of the damage.

8 Germane Consultation and Correspondence

A summary of germane correspondence and consultation related to the Water Level and Flow Effects on Historic Resources Study Report is presented in Table 8-1. Appendix D provides copies of relevant correspondence.

1 Introduction and Background

Boott Hydropower, LLC (Boott or Licensee) is the Licensee, owner, and operator of the 20.2-megawatt Lowell Hydroelectric Project (Project or Lowell Project) (FERC No. 2790). Boott operates and maintains the Project under a license from the Federal Energy Regulatory Commission (FERC or Commission). The Project's existing license expires on April 30, 2023. Boott is pursuing a new license for the Project using the Commission's Integrated Licensing Process (ILP) as defined in 18 Code of Federal Regulations (C.F.R.) Part 5.

In accordance with 18 C.F.R. § 5.15, Boott has conducted studies as provided in the study plan and schedule approved in the Commission's March 13, 2019 Study Plan Determination (SPD) for the Project. This report describes the methods and results of the approved Recreation and Aesthetics Study conducted in support of a new license for the Project.

1.1 Project Description and Background

The Lowell Project is located at river mile (RM) 41 on the Merrimack River in the City of Lowell in Middlesex County, Massachusetts, with an impoundment extending approximately 23 miles upstream into Hillsborough County, New Hampshire. As licensed, the existing Lowell Project consists of:

1) A 1,093-foot-long, 15-foot-high masonry gravity dam (Pawtucket Dam) that includes a 982.5-foot-long spillway with a crest elevation of 87.2 feet National Geodetic Vertical Datum 1929 (NGVD 29) topped by 5-foot-high pneumatically-operated crest gates deployed in five independently-operable zones;
2) A 720-acre[1] impoundment with a normal maximum water surface elevation of 92.2 feet NGVD 29;
3) A 5.5-mile-long canal system which includes several small dams and gatehouses;
4) A powerhouse (E.L. Field) which uses water from the Northern Canal and contains two turbine-generator units with a total installed capacity of 15.0 megawatts (MW);
5) A 440-foot-long tailrace channel;
6) Four powerhouses (Assets, Bridge Street, Hamilton, and John Street) housed in nineteenth century mill buildings along the Northern and Pawtucket

[1] As licensed by the Commission, the impoundment surface area is 720 acres. The actual impoundment surface area is estimated at 1,236 acres.

Canal systems containing 15 turbine-generator units with a total installed capacity of approximately 5.1 MW;

7) A 4.5-mile-long, 13.8-kilovolt transmission line connecting the powerhouses to the regional distribution grid;

8) Upstream and downstream fish passage facilities including a fish elevator and downstream fish bypass at the E.L. Field powerhouse, and a vertical-slot fish ladder at the Pawtucket Dam; and

9) Appurtenant facilities.

At the normal pond elevation of 92.2 feet NGVD 29 (crest of the pneumatic flashboards), the surface area of the impoundment encompasses an area of approximately 1,236 acres. The gross storage capacity between the normal surface elevation of 92.2 feet and the minimum pond level of 87.2 feet (at spillway crest) is approximately 6,180 acre-feet. The Project operates essentially in a run-of-river (ROR) mode using automatic pond level control and has no usable storage capacity.

The Project's primary features are located along the Merrimack River in the City of Lowell, Massachusetts. The City of Lowell was founded in the early 1820s by Boston merchant capitalists and became one of the most significant planned industrial cities in America (Hay 1991). Lowell's factory system, which used the waterpower of the Merrimack River, incorporated new technologies to provide for the mass production of cotton cloth in mills throughout the city (National Park Service [NPS] 1981). Lowell established the pattern for large-scale waterpower development for the next 50 years (Hay 1991).

Several Project facilities are located within overlapping locally, state, and nationally designated parks and historic properties/preservation districts. The Project's Pawtucket Dam and E.L. Field Powerhouse are located along the mainstem of the Merrimack River. The Project's two-tiered network of man-made canals extends throughout downtown Lowell. The 5.5-mile-long canal system provides flow to the Project's Hamilton, Assets, Bridge Street, and John Street developments. The Hamilton, Assets, Bridge Street, and John Street power stations and turbines are housed in large former mill buildings. The mill buildings are not included in the Project; the Project Boundary includes only the turbines and associated waterways and equipment at these downtown mill sites. In addition to the Pawtucket Dam and hydroelectric developments, the Project also includes miscellaneous civil works in the City of Lowell, including the Guard Lock and Gates, Moody Street Feeder Gatehouse, Lawrence Dam, Hall Street Dam, Tremont Wasteway, Lower Locks and Dam, Swamp Locks and Dam, Merrimack Dam and Merrimack Gate, Rolling Dam, and the Boott Dam.

The canal system, the downtown mill sites, and many of the Project's civil works, are contributing resources to Lowell Locks and Canals National Historic Landmark (NHL) District. The canal system and many Project facilities are also located within the Lowell National Historical Park (LNHP) managed by the NPS and the larger Lowell Historic Preservation District. The LNHP was established by Congress in 1978 to "preserve and interpret the nationally significant historical and cultural sites, structures, and districts in

Lowell, Massachusetts, for the benefit and inspiration of present and future generations." The park is by design a partnership park in which federal, state, and local governments as well as the private sector and local community carry out the legislative intent of the park unit. The Lowell National Historical Park is also listed on the National Register of Historic Places (NRHP), and certain properties within the park overlap with properties in the NHL District.

The Lowell Heritage State Park, established in 1974 as a precursor to the LNHP, is also located within the City of Lowell and is comprised of linear greenways along the Merrimack River and canal system and a collection of historic buildings and structures related to the industrial development of the city. These buildings and structures include Project features and properties located within the NHL District. The Lowell Heritage State Park is operated by the Massachusetts Department of Conservation and Recreation (MADCR) and features exhibits created in partnership with the NPS (MADCR 2018). With the exception of the Rynne Bathhouse, all of the built resources within the Lowell Heritage State Park fall within the Lowell Historic District, designated by the City of Lowell to "…ensure that development activities within the district are consistent with the preservation of its 19th century setting" (MADCR 2014). Portions of the Lowell Heritage State Park also overlap with the Lowell Locks and Canals NHL District and the LNHP.

On April 30, 2018, Boott initiated the ILP by filing a Pre-Application Document (PAD) and Notice of Intent (NOI) with the Commission. Major ILP milestones to-date are presented in Table 1-1.

Table 1-1. Major ILP Milestones Completed

Date	Milestone
April 30, 2018	PAD and NOI Filed
June 15, 2018	Scoping Document 1 (SD1) Issued by FERC
July 17, 2018	FERC Agency and Public Scoping Meetings Conducted
July 18, 2018	Project Site Visit Held
September 27, 2018	Scoping Document 2 (SD2) Issued by FERC
September 28, 2018	Proposed Study Plan (PSP) Filed
October 18 & 19, 2018	PSP Meeting Conducted
January 28, 2019	Revised Study Plan (RSP) Filed

February 25, 2020	Initial Study Report (ISR) Filed
March 11, 2020	ISR Meeting
June 12, 2020	FERC Issued Revised Process Plan and Schedule
September 30, 2020	Revised ISR Filed

Date	Milestone
December 2, 2020	Draft License Application (DLA) Filed
February 2, 2021	FERC Issued Determination on Requests
February 25, 2021	Revised ISR Filed
April 30, 2021	Final License Application (FLA) Filed
June 23, 2021	FERC Issued Determination on Requests
November 1, 2021	Updated Study Report (USR) Filed
March 1, 2022	FERC Issued Determination on Requests

Boott has continued consultation with stakeholders regarding the approved studies as required by the Commission's SPD. In accordance with the schedule presented in the RSP, Boott has also provided stakeholders with Quarterly ILP Study Progress Reports that include a description of study activities conducted during the previous quarter, activities expected to occur in the next quarter, and identified variances from the approved study plan.

The Commission's March 1, 2022 Determination on Requests requested the Recreation and Aesthetics Study Report be updated with new information to identify Project effects on recreation. Table 1-2 below provides a roadmap to where FERC and stakeholders can find the study updates included in this report.

Table 1-2. Roadmap to Study Report Updates Based on FERC's March 1, 2022 Determination on Requests

FERC Study Report Update	Boott's Response
(1) a description of boat tour routes used by NPS (past or present) within the Northern and Pawtucket Canal system, including a description of locks or other navigational features that the tours pass through;	See Boott's response in Section 5.5.1.
(2) an evaluation of the effects of Project operation on NPS boat tours in the Northern Canal;	See Boott's response in Section 5.5.1.1.
(3) an evaluation of the effects of Project operation on NPS boat tours, in relation to Boott's proposal to remove the majority of the canal system from the Project boundary;	See Boott's response as it relates to NPS boat tours on the Northern Canal in Section 5.5.1.1. See Boott's response as it relates to NPS boat tours on the Pawtucket Canal in Section 5.5.1.2.

FERC Study Report Update	Boott's Response
(4) an evaluation of the potential for expanding access to the canals for recreation (including NPS boat tours) in light of the results of the Operation Analysis of the Lowell Canal Study and in consideration of Project operation under normal and high flow conditions (including an assessment of surge gate and shut down options);	See Boott's response as it relates to NPS boat tours on the Northern Canal in Section 5.5.1.1. See Boott's response as it relates to public recreational access (including NPS boat tours) to the downtown canal system (i.e. excluding the Northern Canal) in Section 5.4.3.
(5) an analysis of the effects of Project operation on NPS boat tours and recreational rights, in relation to Boott's proposal to remove the majority of the canal system from the Project boundary.	See Boott's response in Section 5.4.1.
Northern Canal Walkway: Identify the number of days that the Northern Canal Walkway would need to be closed seasonally due to flows resulting from Project operation.	See Boott's response in Section 5.5.2.

1.2 Project Recreation Facilities

Pursuant to existing License Article 38 and the FERC-approved Recreation Plan, Boott maintains the E. L Field Powerhouse Visitor Center (Visitor Center). The Visitor Center is the Project's only FERC-approved recreation facility. The Visitor Center offers a secured view of the interior of the turbine gallery and an interpretive display which provides information regarding the development, history, and operation of the Project and nearby historic, natural, cultural, and recreational resources.

Non-Project related recreational facilities and opportunities in the Project's vicinity include the Depot Street Boat Ramp, Greely Boat Ramp, LNHP, Lowell Heritage State Park, Merrill Park, Moore's Falls Conservation Area, and the Rourke Brothers Boat Ramp. The Merrimack River provides extensive recreational opportunities, including boating, canoeing, kayaking, rowing, fishing, and swimming. The surrounding vicinity is used for hiking, picnicking, bird watching, nature study, and overall enjoyment of scenic views.

2 Study Goals and Objectives

The goals of this study are to (a) document recreation resources and recreational activities that occur in the Project area; (b) determine the adequacy and capacity of existing recreational facilities to accommodate proposed enhancements and/or additional recreational activities; (c) assess potential effects of water levels and flow rates on existing recreational facilities; (d) assess the potential for expanded access to the canal system for recreation; and (e) identify areas within the canal system where vegetation growth on historic canal walls and waterborne trash are a concern.

The specific objectives of the study are to:

- Identify existing recreation facilities in the Project area;
- Quantify current recreational use based on recent and new surveys and interviews, and consultation with stakeholders, regional and statewide plans, and other available data (including NPS and MADCR planning documents);
- Identify proposed recreational uses based on surveys and interviews in consultation with stakeholders;
- Evaluate the potential effects of continued operation of the Project (including water levels and flow rates) on recreation resources and activities in the Project area;
- Assess the potential for expanded recreational access to the canal system in consultation with the NPS, MADCR, the City of Lowell, Lowell Parks and Conservation Trust, the Lowell Heritage Partnership, and other partners in recreation;
- Identify areas of concern related to waterborne trash and vegetation growth on historic canal walls and other structures or historic properties owned or under the control of Boott; and,
- Gather information on the condition of Boott's recreation facilities and identify any need for improvement.

3 Study Area

In accordance with the Commission's SPD, the study area for the Recreation and Aesthetics Study is a general area that includes the existing FERC Project Boundary and adjacent recreation facilities (Figure 3-1, Figure 3-2).

Figure 3-1. Existing Project Location and Boundary

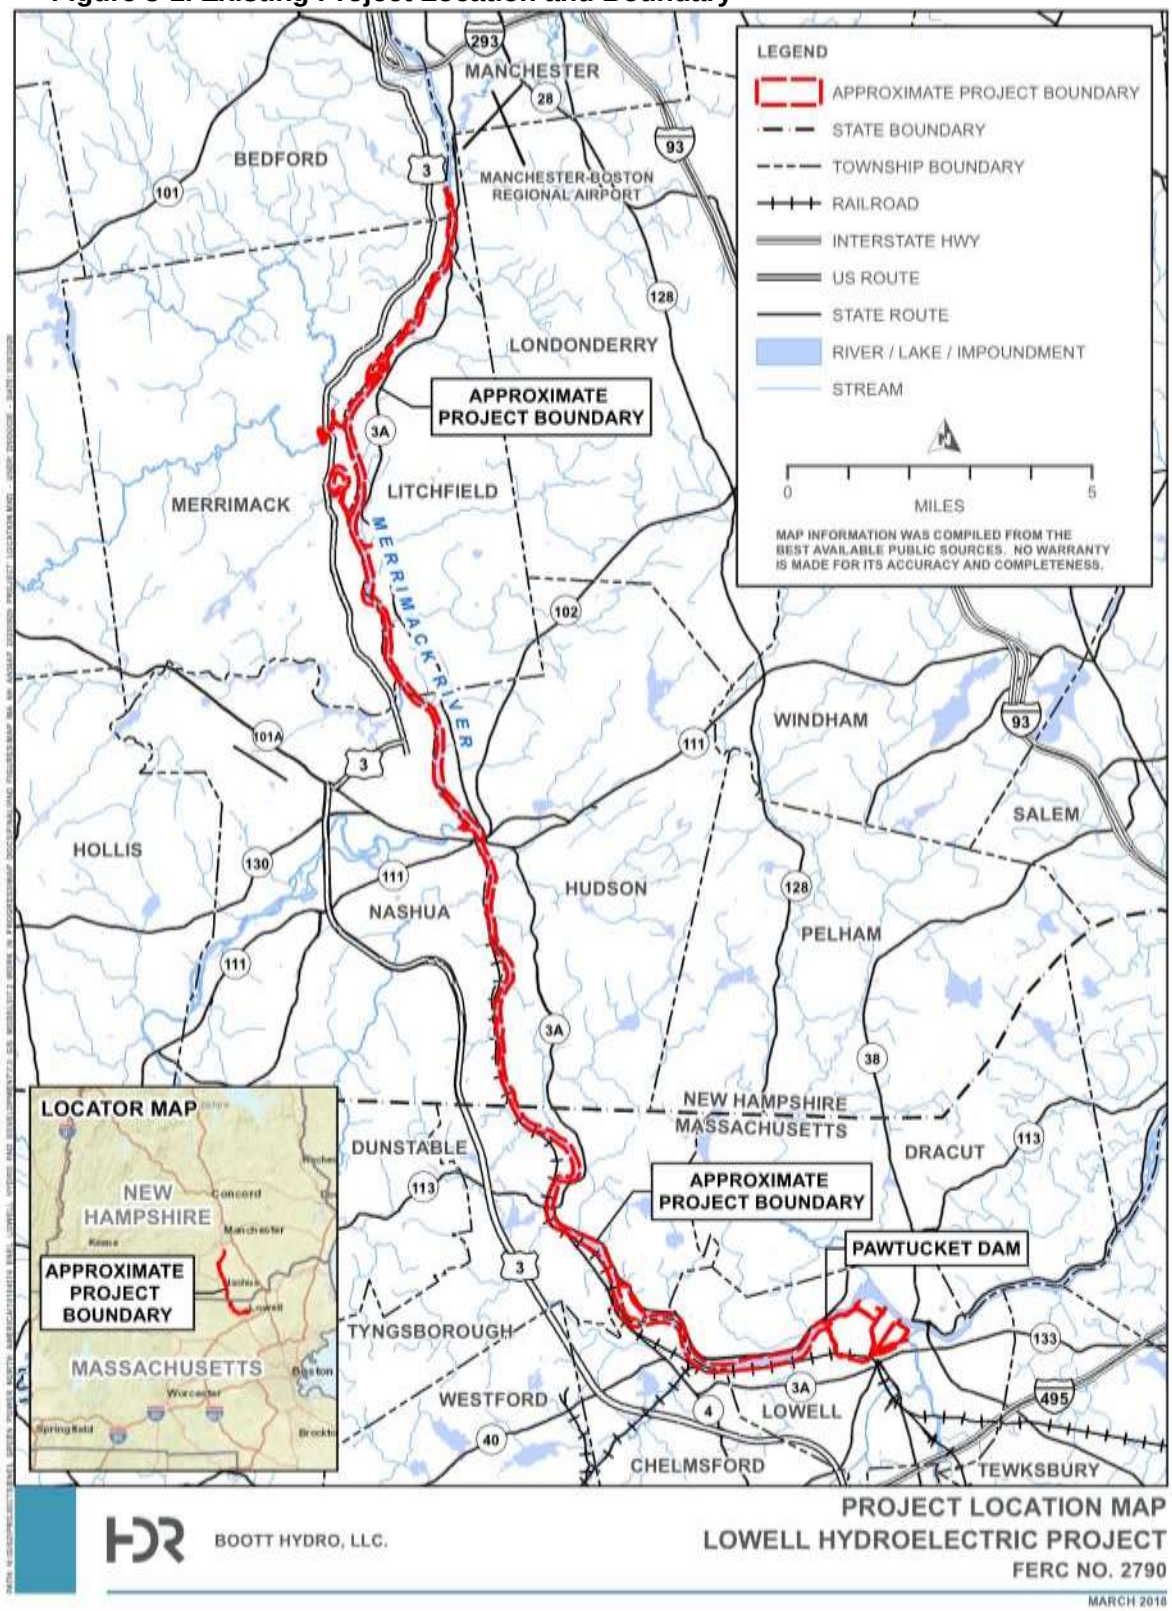

Figure 3-2. Existing Project Boundary and Facilities in Downtown Lowell

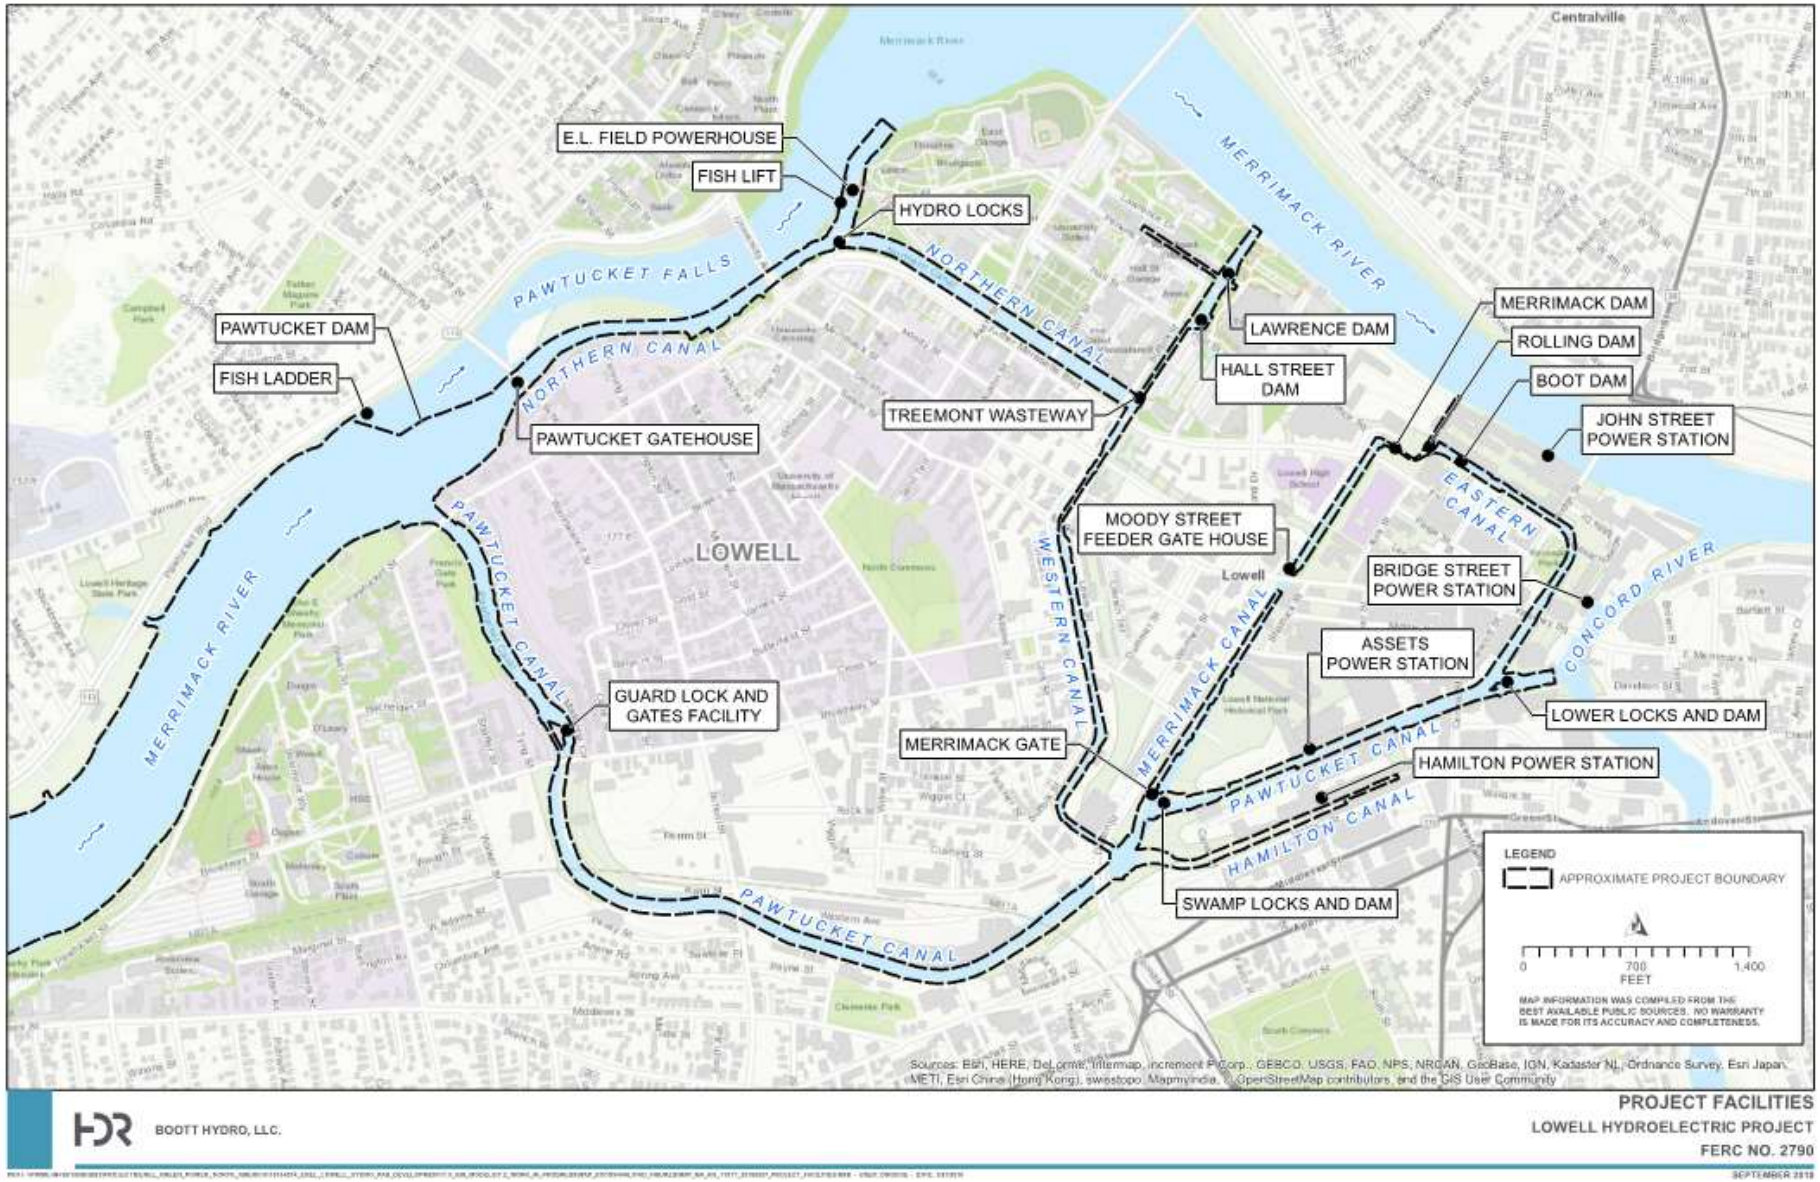


4 Methodology

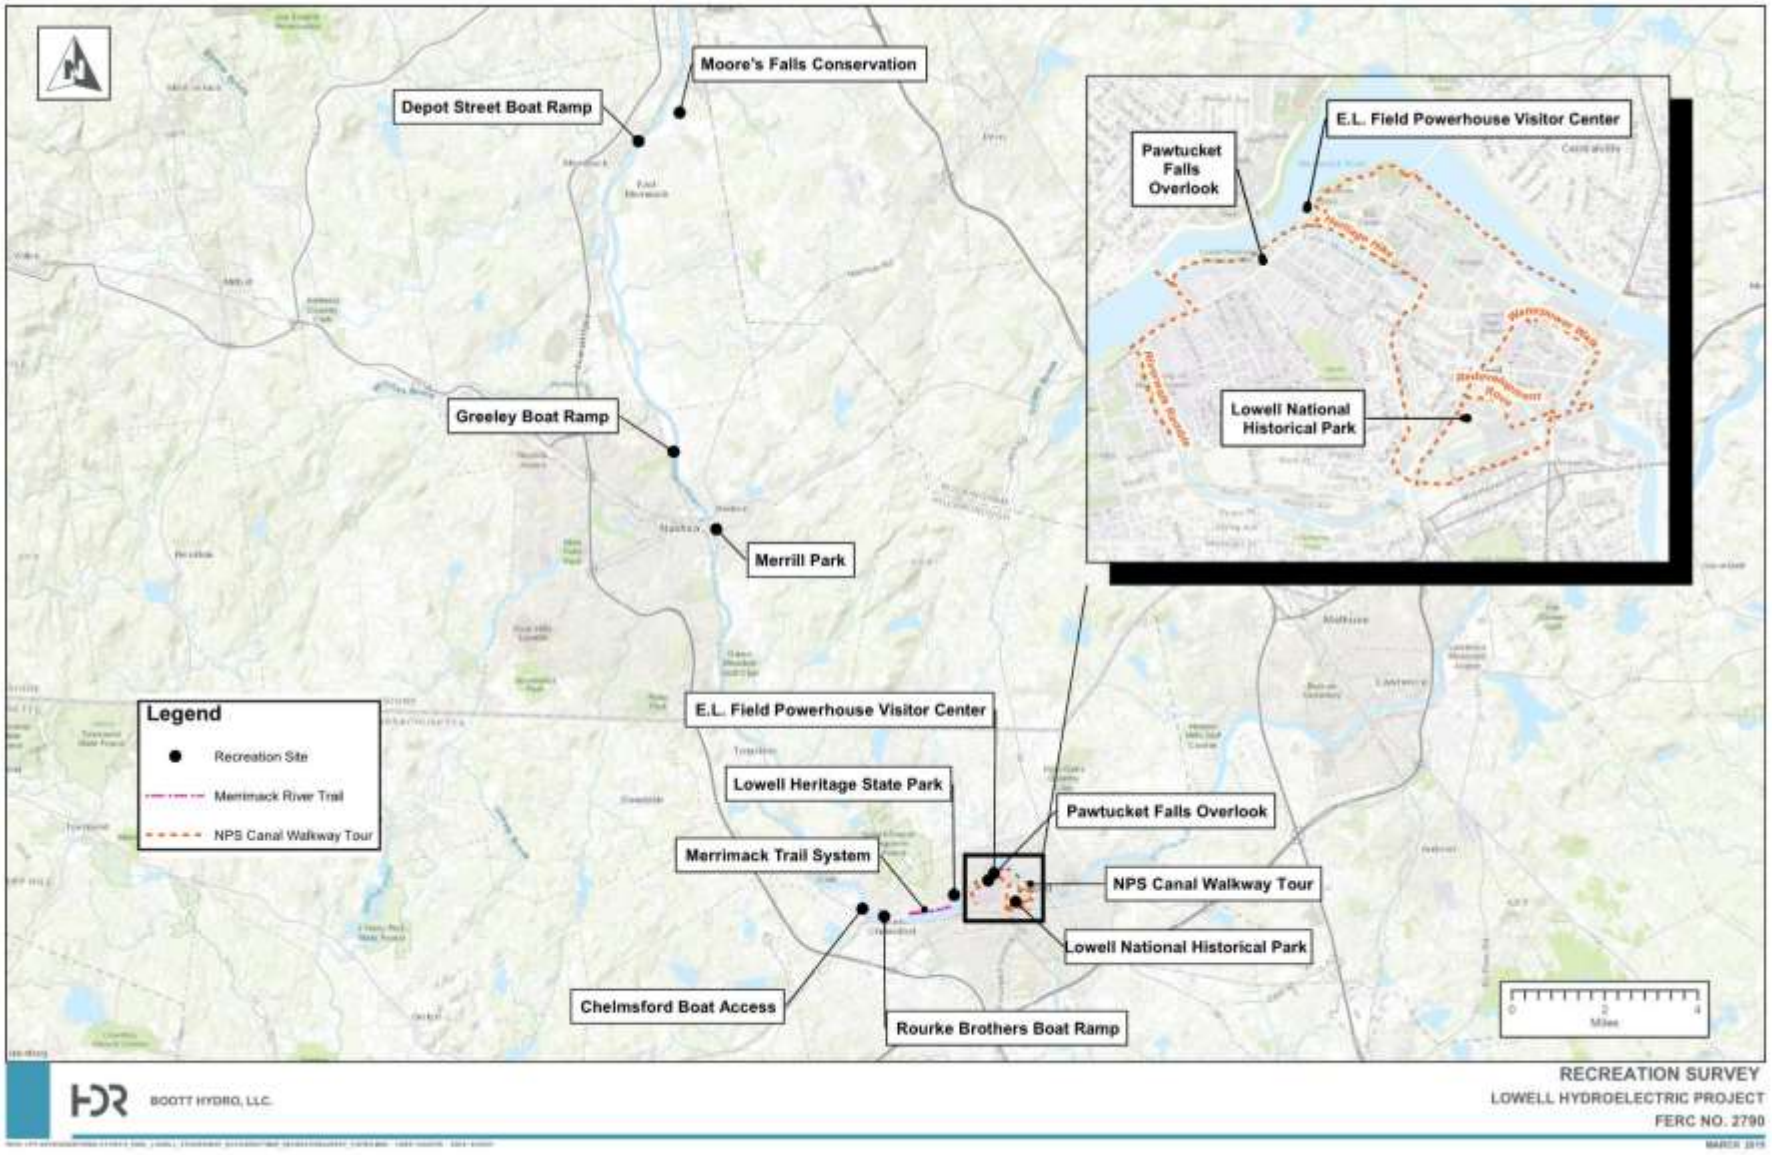
4.1 Literature Review

Boott conducted desktop research and a literature review to identify and describe recreational uses in the Project area, including (but not limited to) whitewater boating, canoeing, kayaking, fishing, swimming, walking, and architectural/historical tours. As a component of this research, Boott reviewed existing recreational uses, facilities management plans (as applicable), and limitations and regulations applicable to the Project area. Additionally, Boott conducted a records search and literature review on the historical and current practices regarding vegetation and waterborne trash management and control on historic canal walls and other structures or historic properties owned or under the control of Boott.

4.2 Field Inventory

Boott conducted a field inventory to document existing non-Project recreation facilities within the Project's vicinity in the fall of 2019. Recreation sites inventoried included the Moore's Falls Conservation Area, Depot Street Boat Ramp, Chelmsford Boat Access, Greeley Boat Ramp, the Rourke Brothers Boat Ramp, Lowell Heritage State Park, Merrimack Trail System, LNHP, Merrill Park, NPS Canal Walkways, and Pawtucket Falls Overlook (Figure 4-1). The Visitor Center, the only Project-related recreation facility, was also inventoried. Pursuant to the RSP, Boott collected information regarding each facility including the type and location of existing recreation facilities, the type of recreation provided (e.g., boat access, angler access, picnicking, etc.), existing amenities and sanitation, the type of vehicular access and parking (if any), the suitability of facilities to provide recreational opportunities and access for persons with disabilities (i.e., compliance with current Americans with Disabilities Act [ADA] standards for accessible design), Global Positioning System (GPS) location data, and representative photographic documentation of recreation facilities.

Figure 4-1. Recreation Field Inventory Locations



4.3 Collection of Visitor Use Data and Field Reconnaissance

4.3.1 Personal Interviews and Field Reconnaissance

As provided in the approved study plan, Boott conducted personal interviews (visitor-intercept surveys) and field reconnaissance activities at recreation facilities in the Project's vicinity between May and October 2019. Boott conducted field reconnaissance and personal interview surveys on random weekdays and weekend days throughout the months of May, June, July, August, September, and October of 2019. Personal interviews and field reconnaissance were conducted on four days of each month on both weekdays, weekend days, and holidays. The actual dates that personal interviews and field reconnaissance took place in 2019 are presented in Table 4-1.

Table 4-1. Personal Interviews and Field Reconnaissance Schedule

Month	Specific Dates
May	• Saturday May 25, 2019 • Sunday May 26, 2019 • Monday May 27, 2019 • Tuesday May 28, 2019
June	• Friday June 7, 2019 • Monday June 10, 2019 • Saturday June 15, 2019 • Sunday June 16, 2019
July	• Wednesday July 10, 2019 • Friday July 19, 2019 • Saturday July 27, 2019 • Sunday July 28, 2019
August	• Tuesday August 6, 2019 • Sunday August 18, 2019 • Wednesday August 21, 2019 • Saturday August 24, 2019
September	• Saturday September 14, 2019 • Thursday September 19, 2019 • Sunday September 22, 2019 • Wednesday September 25, 2019
October	• Wednesday October 9, 2019 • Tuesday October 15, 2019 • Saturday October 19, 2019 • Sunday October 27, 2019

Boott developed survey questions based on general concepts and guidance from the U.S. Forest Service's (USFS) National Visitor Use Monitoring Handbook (USFS 2007) and questions that were asked during recreation studies for other relevant hydropower relicensings. The survey questions that were asked during the personal interviews are included in Appendix A of this study report. Boott consulted with the NPS, MADCR, and

American Whitewater (AW) to identify specific recreation survey locations. The selected locations for the personal interviews and field reconnaissance (Figure 4-1) were:

- Lowell Heritage State Park
- Merrimack Trail System
- Pawtucket Falls Overlook
- NPS Canal Walkways
- LNHP Visitor Center
- Chelmsford Boat Access
- Rourke Brothers Boat Ramp
- Merrill Park, and
- Whitewater takeout location[2]

A team of two technicians traveled between each of the selected recreation sites and spent approximately one hour at each site conducting the personal interviews and collecting field reconnaissance data including (a) the various types of recreation activities, (b) an estimation of the number of vehicles, and (c) the approximate numbers of recreationists observed at each site. Before rotating to the next site, technicians also recorded the date, time, and weather conditions observed. For the personal interviews, individual recreationists and groups were interviewed, including visitors using boat launches and LNHP-managed facilities. Respondents answered questions verbally while a technician recorded their responses using the Qualtrics® offline survey platform to record and submit answers.[3] The personal interview questions included topics such as: general user information; age group, resident/visitor; purpose and duration of visit; distance traveled; history of visiting the site or area; types of recreational activities respondents participated in or planned to participate in during their visit; other recreational sites that respondents visited or intended to visit during their trip; general satisfaction with recreational opportunities, flow conditions, facilities, and the respondents overall visit and/or areas that need improvement; accessibility of facilities or areas; economic aspects, including dollars spent during their trip; and day use/overnight lodging during their visit.

4.3.2 Online Visitor Use Surveys

In addition to the personal interviews, Boott developed a version of the interview questions to allow respondents to provide survey responses online. In accordance with the approved study plan, the survey was made available for one year, from June 2019 to June 2020, on the Project's relicensing website (www.lowellprojectrelicensing.com). The

[2] The Whitewater takeout location is not identified on Figure 4-1. This informal non-Project recreation area is located along the riverfront behind Edward A. Lelacheur Park.

[3] While the survey questions in the approved study plan were utilized for these interviews, the numbering and specific wording was adapted during the interview to better facilitate the interview and to accommodate the Qualtrics® survey platform.

online survey was developed using the Qualtrics® survey platform. Boott posted a brief description of the purpose and intent of the survey and the website address at popular recreation access areas at the Project (Photo 4-1). During personal interviews and field reconnaissance, Boott provided handouts to recreationists with the relevant information on how to access the online survey. Boott notified the Commission and stakeholders of the availability of the online survey in the Second Quarterly Study Progress Report filed with the Commission on October 1, 2019. The survey questions developed for the online survey are also included in Appendix A of this study report.

Photo 4-1. Example of Signage for Participating in Online Visitor Use Surveys

4.4 Evaluation of Expanded Recreational Access in Project Canals

NPS and NPS partners have expressed interest in new, different, and expanded recreational access to and within the Project canals. Boott consulted with the NPS to discuss various recreational opportunities based on the NPS's plans for developing recreational access within the LNHP and the visitor use data collected pursuant to Section 4.3 of this report.

Boott conducted an evaluation of prospective recreation access. This evaluation considered:

- Public safety concerns associated with canal access;

- Infrastructure enhancement that may be required to provide safe public access to the canal system and how such improvements may affect aesthetic and historic resources; and,
- Potential options for improving canal system access, such as operational changes or other measures.

4.5 Documentation of Current Water Levels and Flows

In accordance with the SPD, Boott initiated the data collection associated with the Water Level and Flow Effects on Historic Resources Study and the Operation Analysis of the Lowell Canal Study, both filed with FERC on November 1, 2021. Pressure transducers (level loggers) were installed in the Project's canal system in 2019. On December 18, 2019, Boott held a Lowell Hydroelectric Project Study Workshop (Study Workshop)[4] with stakeholders and refined the data needs for this study based on consultation with the NPS and NPS partners. This included moving the level loggers to locations in the Upper Pawtucket Canal and Northern Canal on March 10, 2020 to better understand and collect data regarding the effects of the crest gate on NPS boat tours and access to the Northern Canal Walkway. These level loggers were removed on September 23, 2020.

4.6 Visual Survey for Vegetation Growth

The visual survey for vegetation growth was conducted between September 25 and 27, 2019. The visual survey was conducted to identify vegetation growth along the canal walls within the study area. Technicians identified the relative quantity and spatial distribution of each vegetation type using aerial photography and observations of habitat and specific plant species occurrences. The methods for this study followed those that were described in the study plan approved by the Commission.

4.6.1 Review of Existing Information

Terrestrial vegetation types occurring in the study area were described based on a review of existing information, an inspection of aerial photography, a review of the U.S. Geological Survey (USGS) 7.5-minute quadrangles, and observations of habitat and specific vegetation type occurrences during the field surveys. Sources of existing information included but were not limited to the following:

- Massachusetts Natural Heritage and Endangered Species Program Classification of the Natural Communities of Massachusetts (Swain 2020): provides a basis for the discussion and conserving the diversity of the types of natural communities and the species they support within the Commonwealth of Massachusetts (Commonwealth). The primary aim of the classification is to describe the natural communities that are

[4] The meeting minutes of the December 18, 2019 Study Workshop were appended to the ISR filed with FERC on February 25, 2020.

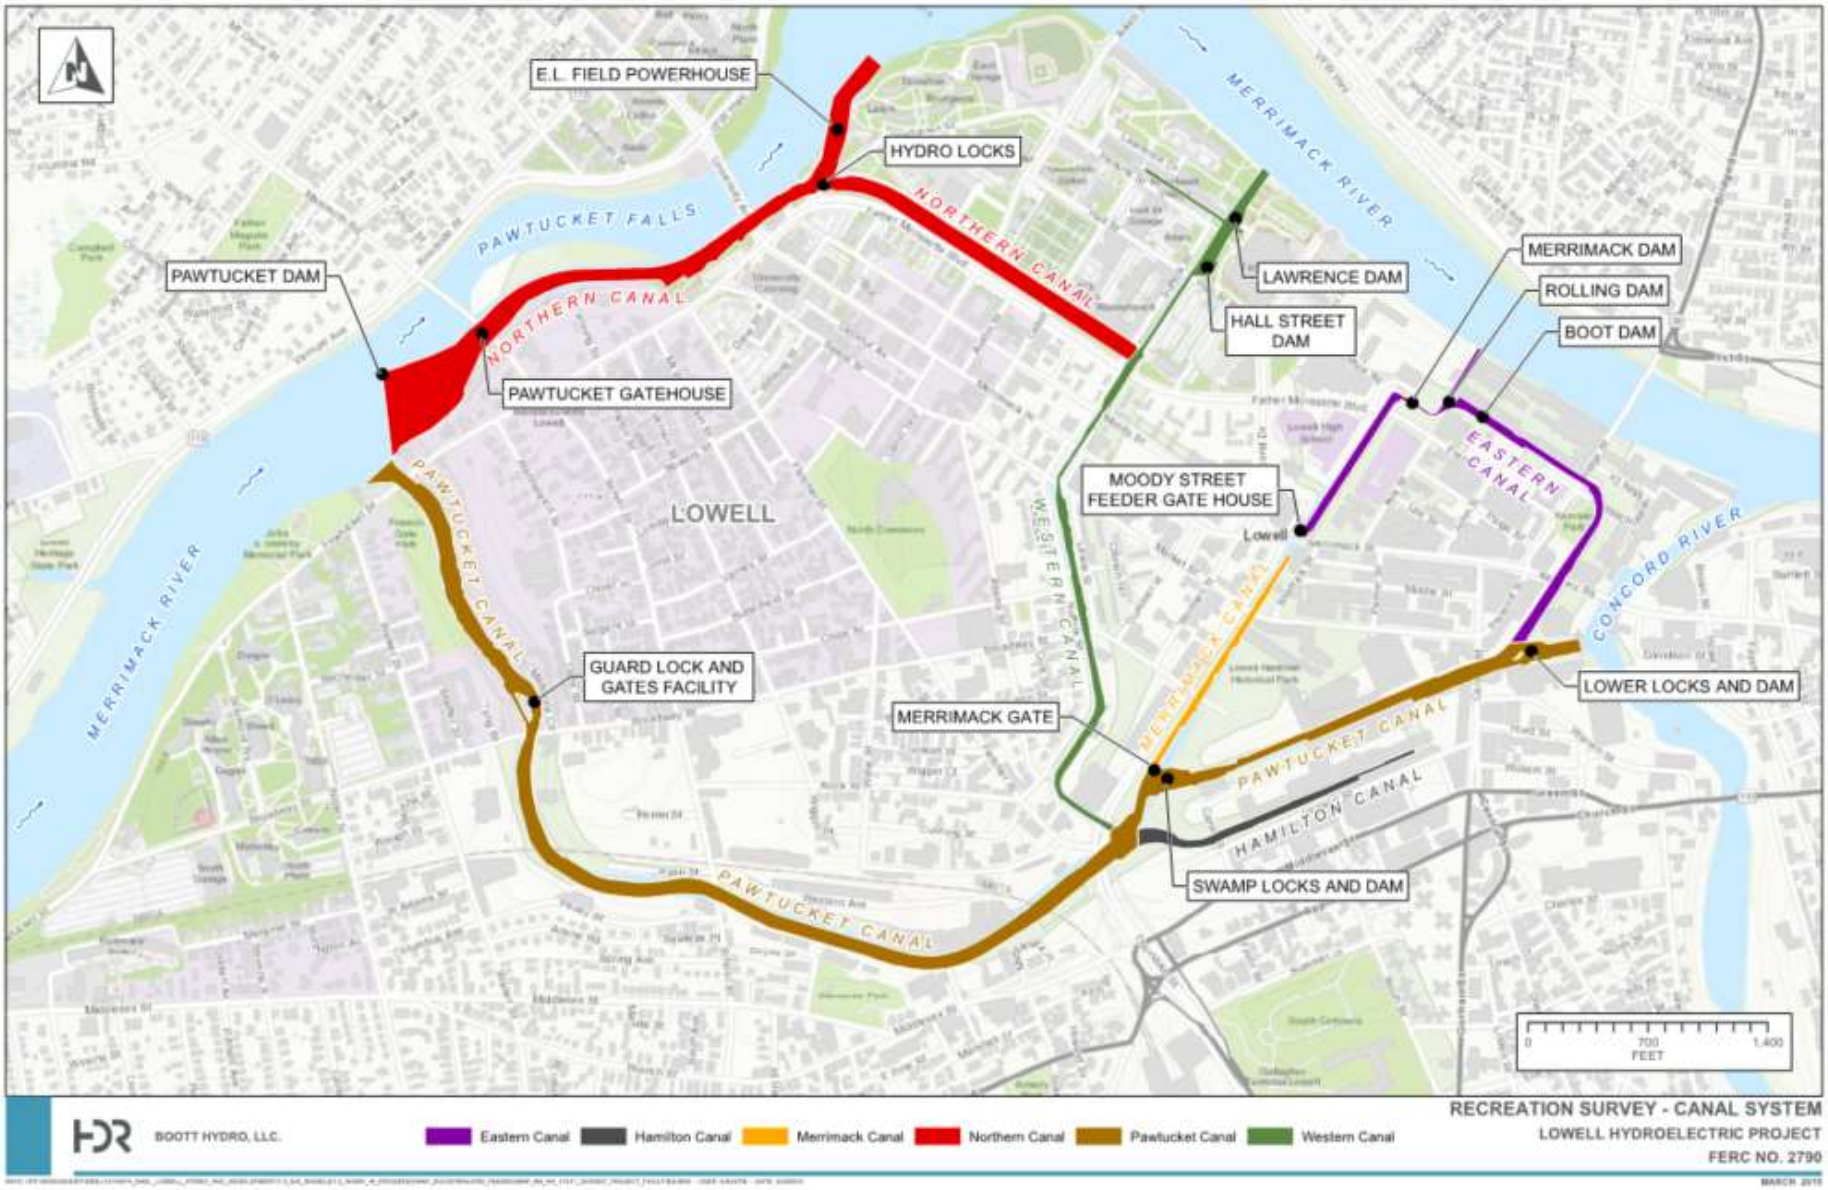
of conservation interest, while also including all types of natural communities in the state.

- Flora of the Northeast – A Manual of the Vascular Flora of New England and Adjacent New York (Magee and Ahles 1999): a reference work and year-round field manual that contains more than 2,400 range maps and over 900 line drawings for identifying the vascular flora of New England and New York.
- Invasive Plants (Kaufman and Kaufman 2007): a guide to the identification and the impacts and control of common North American invasive plant species.

4.6.2 Mapping of Vegetation Growth on Canal Walls

For the purposes of examining vegetation type distribution, the study area was divided into the six canals associated with the Lowell Project canal system including: 1) Pawtucket Canal; 2) Northern Canal; 3) Western Canal; 4) Merrimack Canal; 5) Eastern Canal; and 6) Hamilton Canal (Figure 4-2).

Figure 4-2. Visual Survey for Vegetation Growth Study Area



Visual qualitative surveys were conducted in the study area by foot along the shorelines of the canals, or via an NPS boat for the surveys conducted in the Pawtucket Canal from the Swamp Locks and Dam to the Merrimack River. Vegetation was characterized by dominant type (i.e., Herbaceous, Scrub-Shrub, Trees, Forested, or Mixed) (Table 4-2). The vegetation type assessments were based on overall dominant vegetation characteristics at the time of the survey that may have variations within small areas. In addition, the shoreline/canal was characterized by dominant features (i.e., Block Wall, Concrete, Earthen/Terrestrial Cultural, Stone Wall, Block Wall/Concrete/Stone Wall Mix) (Table 4-3). The shoreline/canal type assessments were based on overall dominant features at the time of the survey that may have variations within small areas.

Table 4-2. Dominant vegetation types used during field surveys

Vegetation Type	Description
Herbaceous	Characterized by primarily herbaceous (non-woody) plants, including herbaceous vines, regardless of size, and woody plants less than 3 feet tall.
Scrub-Shrub	Consists of woody plants less than 3 inches diameter at breast height (DBH) and greater than or equal to 3 feet tall.
Trees	Consists of woody plants 3 inches or more in DBH, regardless of height. This vegetation type description was generally used to describe areas along canal walls where only a few trees were growing in a clump.
Forested	Characterized as a relatively large area that consists of primarily trees and underbrush.
Mixed	Characterized by a mosaic of herbaceous, scrub-shrub, and/or trees.

Table 4-3. Dominant shoreline/canal types used during field surveys

Shoreline/Canal Type	Description
Block Wall	Canal walls primarily dominated by placed, generally uniform sized blocks with concrete caps or block alone.
Concrete	Canal walls primarily dominated by concrete, with various types of cement and aggregate.
Earthen/Terrestrial Cultural	Canal walls generally dominated by earthen embankments (forested and unforested) and areas of exposed bedrock. Some of these areas (e.g., riprapped areas) have been created and/or maintained by human activities.
Stone Wall	Canal walls primarily dominated by placed, generally non-uniformly sized blocks with concrete caps or block alone.
Block Wall/ Concrete/Stone Wall Mix	Areas of canal walls predominantly composed of a conglomeration of block wall, concrete, or stone wall at varying quantities.

Mapped Vegetation Polygons and Vegetation Points (VPs)[5] were located using an EOS Positioning Systems Arrow 100™ GNSS receiver linked to an iPad™ Air 2 or Android device operating Collector for ArcGIS™ hand-held GPS unit (equipped with a data dictionary aiding in feature attribution). The presence and extent of cover of the vegetation on/along the canal walls observed at the time of the field survey was evaluated based on photographs and field observations. Geospatial vegetation data were transferred to a Geographic Information System (GIS) format and used to develop both visual maps depicting vegetation presence boundaries and VPs along the canal walls as well as tabular information quantifying the abundance and distribution of dominant vegetation types in the study area. Vegetation polygons were then analyzed to calculate the percentage represented by each vegetation category within each canal; VPs were not included in vegetation category percentage calculations because they represent a single point on the canal wall.

Each representative vegetation type was photographed. Each vegetation polygon and VPs, including any canal descriptive features (e.g., riprap, concrete walls, earthen embankments, etc.) within a polygon or near a VP, was photo documented when possible.

4.6.3 Data Analysis and Processing

During the field effort, mapped vegetation type polygons were collected to represent current conditions. Vegetation type boundaries were mapped to reflect field observations of vegetation composition.

Upon completion of the field data collection effort, all data were checked for errors and omissions. The percentages of each vegetation type were calculated. Minor adjustments were made to a small number of vegetation polygon boundaries and subsequent percentages based on examination of the location of the GPS polygon data relative to banks and bends along the canals, or from recorded field data during mapping.

4.7 Visual Survey for Waterborne Trash

The visual survey for waterborne trash was formally conducted on April 9, 2020. The survey was conducted to identify locations within the study area where waterborne trash accumulates within the Project Boundary. Waterborne trash occurring along the canals was described based on observations of accumulated waterborne trash during the field reconnaissance survey. The methods for this study followed those that were described in the study plan approved by the Commission.

[5] Vegetation points were used to identify areas along canal walls where a single vegetation type point was recorded. Vegetation points generally identify where a single species (e.g., shrub, tree) was located.

4.7.1 Review of Existing Information

Areas of waterborne trash occurring in the study area were described based on a review of existing information, an inspection of aerial photography, the observation of accumulated waterborne trash during other Project relicensing studies, a review of information provided to Boott by the NPS that identifies areas of trash accumulation (both on the canal bottom and waterborne) within the study area, as well as the specific waterborne trash occurrences during the field survey.

4.7.2 Waterborne Trash Mapping

For the purposes of examining waterborne trash accumulation areas, the study area was divided into the six canals associated with the Lowell Project canal system including: 1) Pawtucket Canal; 2) Northern Canal; 3) Western Canal; 4) Merrimack Canal; 5) Eastern Canal; and 6) Hamilton Canal, and associated NPS gatehouses and locks (Figure 4-2).

Visual qualitative surveys were conducted in the study area by vehicle as well as on foot along the shorelines of the canals. Waterborne trash was characterized by dominant type (i.e., Plastics/Household, Woody Debris, or Assorted) (Table 4-4). The canal level (low, medium, high) at the time of the site investigation was also recorded. The waterborne trash assessments were based on the overall dominant trash type observed at the time of the survey.

Table 4-4. Dominant Waterborne Trash Types Used During Field Surveys

Waterborne Trash Type	Description
Plastics/Household	Characterized by plastic cups, plastic bags, wrapping materials, plastic water bottles, plastic containers, rubber balls, fast-food wrappers, shoes, construction barrels, etc.
Woody Debris	Characterized by trees, logs, branches, stumps, boards, sections of plywood, etc.
Assorted	Characterized by a conglomeration at varying densities of plastics/household and woody debris.

Mapped areas of waterborne trash were located using an EOS Positioning Systems Arrow 100™ GNSS receiver linked to an iPad™ Air 2 or Android device operating Collector for ArcGIS™ hand-held GPS unit (equipped with a data dictionary aiding in feature attribution). The presence and extent of waterborne trash within the canals observed at the time of the field survey was evaluated based on field observations and photographs. Geospatial waterborne trash data were transferred to a GIS format and used to develop both visual maps depicting mapped areas of accumulated waterborne trash within the canals as well as tabular information describing the abundance and distribution of waterborne trash in the study area. The mapped polygons were then analyzed to calculate the area represented by each dominant trash type within each canal.

Each representative trash type was photographed. Each waterborne trash polygon, including any canal descriptive features (e.g., active construction adjacent to canal, primarily residential, commercial, etc.) in the vicinity of a polygon, was photo documented when possible.

4.7.3 Data Analysis and Processing

During the field effort, mapped waterborne trash polygons were collected to represent current conditions. Waterborne trash polygon boundaries were mapped to reflect field observations at the time of the investigations.

Upon completion of the field data collection effort, all data were checked for errors and omissions. The areas of each mapped waterborne trash polygon were calculated. Minor adjustments were made to a small number of mapped waterborne trash polygon boundaries and subsequent areas based on examination of the location of the GPS polygon data relative to banks and bends along the canals, or from recorded field data during mapping.

5 Study Results

5.1 Literature Review

Pursuant to the approved study plan, Boott reviewed several sources to summarize recreation in the Project area, including the Massachusetts Statewide Comprehensive Outdoor Recreation Plan (SCORP) (Massachusetts Executive Office of Energy and Environmental Affairs [MEOEEA] 2017); the New Hampshire Department of Natural and Cultural Resources (NHDNCR) SCORP 2018; the Massachusetts Recreational Trails Program Guide (MassTrails) 2020; the LNHP Foundation Document (LNHP 2017); The City of Lowell Open Space and Recreation Plan (City of Lowell 2018); and the City of Lowell's Comprehensive Master Plan, known as Sustainable Lowell 2025 (City of Lowell 2013). Additionally, Boott conducted a records and literature review on the historical and current practices regarding management of vegetation growth and waterborne trash. This section summarizes the results of the literature review to characterize these aspects in the Project area.

5.1.1 Recreation in the Project Area

The Merrimack River provides widespread recreational opportunities. The 116-mile-long Merrimack River begins at the confluence of the Winnipesaukee and Pemigewasset Rivers in the City of Franklin, New Hampshire, flows southward into Massachusetts, and then travels northeast until it discharges into the Atlantic Ocean (New Hampshire Department of Environmental Services [NHDES 2019]). Although the Merrimack River watershed is heavily forested (75% of the land area is covered with forest), it also supports all or parts of approximately 200 communities with a total population of 2.6

million people (Environmental Protection Agency [EPA] 2020; U.S. Army Corps of Engineers [USACE] 2006). The Merrimack River provides numerous recreational opportunities to the residents of the communities along its banks but is also utilized by residents of major cities in the region, particularly residents from Boston (Nashua Regional Planning Commission [NRPC] 2008; NHDES 2019; USACE 2006).

The Project dam is located at river mile 41 on the Merrimack River, and the impoundment extends upstream approximately 23 miles almost to the City of Manchester in New Hampshire. The Project impoundment is characterized by the urban/industrialized cities of Nashua, New Hampshire and Lowell, Massachusetts. Recreational opportunities differ closer to these larger, more populated cities along the river. The State of New Hampshire reports many recreational uses of the Project impoundment, including fishing, canoeing, kayaking, rowing, and motor boating. Lands adjacent to the Project impoundment are used for hiking, picnicking, birdwatching, nature study, and overall enjoyment of the scenic views (NHDES 2019; NHDNCR 2018; New Hampshire Fish and Game Department [NHFGD] 2020; NHFGD 2016).

The state of Massachusetts reports that recreation along the Project impoundment changes as open space generally decreases further downstream and riverfront communities are more industrialized (MEOEEA 2001). Water-based recreation (boating, fishing, canoeing, and swimming), is provided on the downstream portion of the Project impoundment by multiple boat ramps and waterfront parks. The City of Lowell, NPS, and MADCR report many additional recreational opportunities in and surrounding Lowell, including networks of trails, thousands of acres of nearby state forest, and urban passive parks for walking, jogging, dog-walking, and picnicking (City of Lowell 2018; MADCR 2014; LNHP 2017). As part of the LNHP or Lowell Heritage State Park, different sites in and around the city of Lowell are related to the historical era of textile manufacturing and offer museum exhibits, walking tours, and interpretive/interactive displays (LNHP 2017; MADCR 2014).

Although portions of the LNHP are within the Project boundary, it is not a FERC-approved recreation facility. As noted above in Section 1.2, the Visitor Center is the Project's only FERC-approved recreation facility. The Visitor Center offers a secured view of the interior of the turbine gallery and an interpretive display which provides information regarding the development, history, and operation of the Project and nearby historic, natural, cultural, and recreational resources.

Recreational opportunities available along the 23-mile impoundment are summarized in Table 5-1 and described in more detail below.

Table 5-1. Recreational Opportunities Available on the Project Impoundment

Recreational Facility	Canoe/Kayak Access	Boat Ramp	Picnic Area	Fishing Access	Trail System	Light Trails	Designated Swimming Area	Visitor Center	Historical/Heritage Exhibits
Moore's Falls Conservation Area	✓		✓	✓	✓	✓			
Depot Street Boat Ramp	✓		✓	✓					
John Bryant River Access	✓		✓	✓					
Thornton's Ferry Boat Launch	✓			✓					
Greeley Park & Boat Ramp	✓	✓	✓	✓	✓	✓			
Merrill Park	✓		✓	✓		✓			
Chelmsford Boat Access	✓	✓	✓	✓	✓				
Rourke Brothers Boat Ramp	✓	✓		✓					
Lowell Heritage State Park			✓	✓	✓	✓	✓		✓
Pawtucket Falls Overlook									✓
Lowell National Historical Park					✓	✓		✓	✓
E.L. Field Powerhouse Visitor Center								✓	✓

Much of the Project impoundment is in Hillsborough County in New Hampshire. The New Hampshire SCORP estimated that the county has approximately 54,480 acres of recreation lands and 116 public access sites to the water. Public lands maintained by state, federal, or local municipalities comprise the majority of identified recreational acreage in the county, followed by private non-profit organizations/land trusts. With an estimated 197 natural/passive recreation areas and 111 parks, picnics, and playground areas, Hillsborough County has the most of all counties in New Hampshire. Given the national trend of individuals choosing to recreate closer to home, the New Hampshire

SCORP states it is important that larger population bases, such as that of Hillsborough County, have higher proportions of recreation sites (NHDNCR 2018).

Most of the shore lands along the Merrimack River in New Hampshire are privately owned. Activities such as boating, canoeing, kayaking, rowing, and fishing take place immediately on the Merrimack River (NRPC 2008). There are six known boat access facilities in New Hampshire with direct access to the Project impoundment. These facilities range in design from concrete ramps to shoreline access and are described below:

Moore's Falls Conservation Area: Moore's Falls Conservation Area offers shoreline fishing and car-top boating access to Moore's Falls in the Project impoundment. Moore's Falls are a length of rapids on the Merrimack River which drop 6 feet in elevation over 650 feet in distance. There are also walking trails through the woods, an old trolly track trail, multiple access points to the Merrimack River for fishing, educational information regarding environmental conservation, and birdhouses. NHDES recommends this conservation area for angler fishing, as small and large mouth bass are often caught, as well as rainbow and brook trout, both of which are stocked by the NHFGD in the Lower Merrimack River (Middlesex Canal Association 2009; NHDES 2019).

Depot Street Boat Ramp: The Depot Street Boat Ramp offers a carry-in boat ramp and fishing access to the Merrimack River and is managed by the Town of Merrimack. The trail to the river runs under railroad tracks. This access is suitable for motorboats, as the river slows from the rocky rapids upstream (NHDES 2019; Merrimack Parks and Recreation 2020). There is also a scenic picnic area.

John Bryant River Access: The John Bryant River Access is a canoe/kayak car top facility managed by the Litchfield Recreation Commission. It provides fishing access, scenic views of the river, and birdwatching. It is available only to Town of Litchfield, New Hampshire residents (Litchfield Recreation Commission 2020).

Thornton's Ferry Boat Launch: Thornton's Ferry Boat Launch is owned by the Town of Merrimack and offers cartop carry-in boating and fishing access to the Merrimack River (NHFGD undated).

Greeley Park & Boat Ramp: Greeley Park is a 125-acre city park located in Nashua, New Hampshire. Greely Park offers many recreation amenities/facilities including baseball/softball fields, historical sites, picnic areas, playgrounds, restrooms, tennis courts, trails, and wading pools (NHFGD undated; City of Nashua 2020). In 2019, the City of Nashua issued an invitation to bid for reconstruction of the Greeley Park Boat Ramp, as well as construction of a gravel parking lot, placement of new signs, and three biological retention ponds. The work was scheduled for completion in July 2020 (NHFGD undated; City of Nashua 2019). A paved ramp at the north end of Greeley Park in Nashua also allows access to the river for boaters. NHDES recommends this conservation area for angler fishing (NHDES 2019).

Merrill Park: Merrill Park is a 9.3-acre city park located in Hudson, New Hampshire. It is adjacent to the east riverbank and Project boundary. The park is mostly forested with a few walking paths and picnic benches. It has a path which leads down to the Merrimack River, allowing hand-carry access for canoes or kayaks, or fishing (Town of Hudson undated).

The Merrimack River provides quickwater and flatwater experiences for canoeists and kayakers and is one of the largest surface water bodies in the region for motor boating. Local watershed organizations sponsor a variety of paddling trips on the Merrimack River and its tributaries throughout the spring, summer, and fall for beginner and intermediate paddlers (NHDES 2017). Upstream of the northern extent of the Project impoundment is a whitewater kayak course located in Manchester, New Hampshire. There are also class I-II+ rapids located between Amoskeag Falls to Goffs Falls (City of Manchester 2018).

The most popular outdoor activities for New Hampshire residents include wildlife observation, driving for pleasure, sightseeing, and jogging/running/walking. Day hiking tends to be more popular in New Hampshire than the national average (NHDNCR 2018). Natural areas in the vicinity of the Project in New Hampshire are also used for cross country skiing, picnicking, bird watching, nature study, and overall enjoyment of scenic views (NRPC 2008). In addition to the facilities mentioned above, the following facilities are within a 30-minute drive from the Project impoundment and are provided for these types of activities:

Litchfield State Forest: The Litchfield State Forest is a 450-acre forest in Litchfield managed by the State of New Hampshire. It is located about 1.5 miles east of the Project boundary. The 1.3-mile Litchfield State Forest Trail provides comfortable walking and biking trails. Off trails provide an additional four miles of hiking, wildlife observation, and scenic opportunities. The trails are often used for cross country skiing in the winter (Litchfield Recreation Commission 2020; ExploreYourSpaces 2020).

Flints Pond Access: Flints pond is a 50-acre, warm water pond located in the Town of Hollis in New Hampshire. The pond is open to the public for fishing, kayaking, and canoeing in the summer. In the winter, ice fishing, snowshoeing, and snowmobiling are also popular. A boat ramp is available at the north end of the pond (Flints Pond Improvement Association 2015). Flints Pond Access is approximately 0.2 miles west of the Project boundary.

Horse Hill Nature Preserve: Horse Hill Nature Preserve is a 560-acre property owned by the town of Merrimack, located about three miles west of the Project Boundary. It is primarily a mixed hardwood forest, with a series of streams, ponds, swamps, and numerous wetlands. Old logging roads form the basis of what is today a trail network used by hikers, bikers, cross country skiing, snowshoeing, hunters, snowmobilers, and horseback riders. This trail network covers most of the property, however, there are still large areas without defined access.

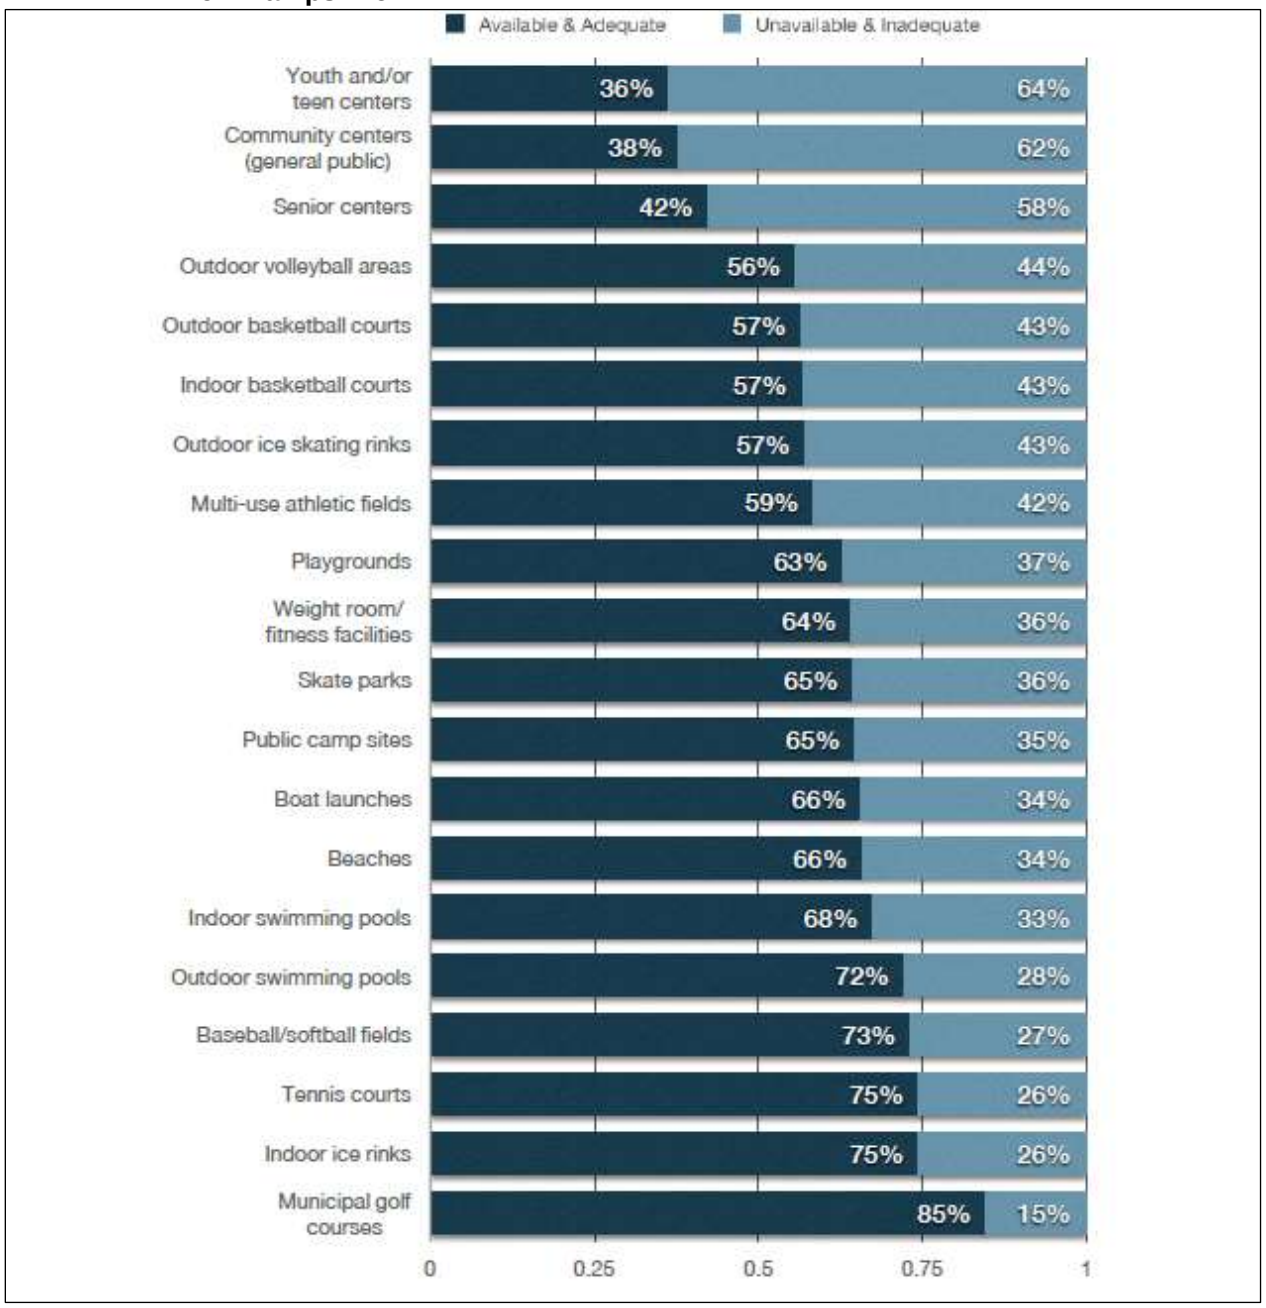
Leslie Bockes Memorial Forest: Forest Society owns and manages this approximately 226-acre forest located in Londonderry, New Hampshire (five miles east of the Project boundary). Nearly four miles of old logging roads provide hiking, skiing, and snowshoeing with numerous access points. The trails are on well-maintained woods roads that enable easy walking and generally good footing. The tract is a known spot for bird and nature-watching (Forest Society 2020).

Twin Bridge Park: Twin Bridge Park is in Merrimack, New Hampshire, and features a baseball field, playground, picnic area, and extensive hiking trails through 27 acres of woods along Baboosic Brook (Town of Merrimack undated). Twin Bridge Park is approximately 0.2 miles west of the Project boundary.

New Hampshire Heritage Trail: The completed trail system will connect trail segments along the Lower Merrimack River and ultimately extend south into Massachusetts, and north along the Merrimack, Pemigewasset, and Connecticut Rivers to the Canadian border. Several trail sections have been completed along this part of the river and northward, with existing segments in Nashua, Hooksett and Manchester, New Hampshire (NHDES 2019).

The most recent New Hampshire SCORP was developed in 2018 for the 2019-2023 program years (NHDNCR 2018). The primary goals of the New Hampshire SCORP are to identify outdoor recreation trends, needs, and issues for New Hampshire, as well as to provide a strategic plan to address changing recreation needs, conservation of natural resources, and the economic vitality of communities. Municipal officials in New Hampshire reported the availability and adequacy of developed recreation facilities and amenities to meet needs within their communities. Figure 5-1 below shows the facilities in order of greatest need in New Hampshire. Municipal officials reported youth and/or teen centers as least available and adequate to meet growing needs, while reporting indoor ice rinks and municipal golf courses as most available and adequate to meet needs. The most relevant to the Project of these rated recreation facilities and amenities in New Hampshire are state/municipal parks, beaches, boat launches, and public camping sites, all of which were identified as being at least moderately available and adequate to meet recreation needs (>50%).

Figure 5-1. Availability and Adequacy of Developed Recreation Facilities/Amenities in New Hampshire



Source: NHDNCR 2018

The Massachusetts SCORP (MEOEEA 2017) is a planning document that discusses the available recreational resources in a state, as well as its changing recreation needs. In drafting of the SCORP, the Massachusetts Executive Office of Energy and Environmental Affairs hosted a series of public meetings across the state in the fall of 2017. Online surveys were also utilized to gather input from both residents and recreation providers. Around 780 citizens responded to the resident survey and 58

municipalities and 38 land trusts responded to the recreation provider survey. The Massachusetts SCORP categorized the most common recreational activities as either water-based recreation (e.g. boating, fishing, swimming at beach/lake/river) or trail-based recreation (e.g., hiking, biking, cross-country). The nearness of an outdoor recreation facility to home was the top reason that it was visited most frequently. Accordingly, when asked to identify the most-needed improvements, recreationists identified trail and water-based recreation enhancements. Massachusetts municipalities reported the highest funding priorities for the next five years are playgrounds, ballfields (soccer, lacrosse, baseball, etc.), community or regional trail systems, and improved pedestrian access to parks (sidewalks, safe road crossings, etc.).

The downstream portion of the Project impoundment is accessible for water-based recreation by the following recreational facilities in Massachusetts:

Lowell Heritage State Park: The 83-acre Lowell Heritage State Park occupies a 2-mile long stretch along the north bank of the Project impoundment, upstream of the Pawtucket Dam. The park features historical exhibits that were created in partnership with the NPS to educate the public regarding the network of canals and mills constructed in the 19th century to power Lowell's then bustling textile industry. Activities available include biking, boating (non-motorized and motorized), canoeing and kayaking, swimming, fishing, hiking, and educational programs. Facilities include a paved bike path and walking esplanade, picnic area, a beach, restrooms, scenic viewing area, an outdoor concert stage, and visitors center (Commonwealth of Massachusetts 2018a). Also located within the park boundary is the University of Massachusetts Lowell Bellegarde Boathouse, which also houses the Merrimack River Rowing Association, a non-profit rowing club.

Rourke Brothers Boat Ramp (part of the Lowell Heritage State Park): The park provides a trailered boat launch, located on the north bank of the impoundment about 2 miles upstream of the Pawtucket Dam. Adjacent to the boat launch is an access dock for boating and fishing.

Chelmsford Boat Access: The park provides a trailered boat launch, shoreline fishing access, picnic areas, athletic fields, and trails.

The Resource Management Plan (RMP) for the MADCR Lowell/Great Brook Planning Unit (MADCR 2014) reports the following recreational facilities within the planning unit, located within a 30-minute drive from the Project boundary:

Lowell-Dracut Tyngsborough State Forest: The Lowell-Dracut Tyngsborough State Forest is approximately one mile north of the Project boundary. The Lowell-Dracut Tyngsborough State Forest spreads across three towns and features over 1,140 acres of protected land, including 180 acres of open water or wetlands and 457 acres of land in the city of Lowell. Popular activities include hiking, fishing, hunting, cycling, birding, picnicking, nature walking, mountain biking, and playing various field sports. In the

winter, people sled, ice skate, and cross-country ski (Commonwealth of Massachusetts 2018b).

Great Brook Farm State Park: Located seven miles south of the Project, this park is a working dairy farm connected to miles of trails that can be used for a variety of recreational activities. The park also includes historic buildings and resources, interpretive programming, and a cross-country ski concession.

Warren H. Manning State Forest: Located five miles south of the Project, this state forest is a largely wooded property with a small recreation area, complete with a spray deck, picnic area, water playground, and fitness trail.

Billerica State Forest: Located six miles south of the Project, this state forest offers rustic, multi-use trails and wooded areas for walking and wildlife viewing.

Carlisle State Forest: Located ten miles south of the Project, this state forest provides over a mile of trails through wooded property protected from forestry activities at the turn of the 20th century. The forest includes an older stand of exceptionally large eastern white pines.

Governor Thomas Dudley State Park: Located ten miles south of the Project, this 11-acre park is a small wooded parcel that provides access to the Concord River and links to other protected open spaces.

At the state level, the focus of outdoor recreation tends to be on recreation lands and facilities outside of urban areas. This is evidenced in the Massachusetts SCORP and MADCR's RMP for the area, which primarily discuss and address recreation in open undeveloped areas like state lands and forests.

Sustainable Lowell 2025 and the 2018 Lowell Open Space and Recreation Plan (OSRP) prepared by City of Lowell, estimates there are 463 acres of open space/recreational land owned or maintained by the city. The City of Lowell reports a variety of recreational amenities including sports facilities (basketball, tennis, softball, swimming, and skateboarding), passive parks for walking, jogging, dog-walking, and picnicking, community gardens, playgrounds, multiuse trails, and greenspaces. City-funded cemeteries provide an additional 222 acres of open space to Lowell residents and visitors (City of Lowell 2018). The City of Lowell has also collaborated with the LNHP to secure funding for and manage the development and redevelopment of 6,662 linear feet of canal walkways throughout Lowell, with work on an additional 11,360 linear feet underway (City of Lowell 2018).

The Concord River Greenway is still in development, but to date has 2,700 linear feet of trail and 1.3 acres of open space cutting through the City of Lowell. Public art and interpretive signs line the multi-modal path. Once complete, the Concord River Greenway will link to a network of trails in the area, including the Bay Circuit Trail, a 200-mile trail from coastal Boston to Kingston, as well as the Bruce Freeman Rail Trail from

Lowell to Framingham. It will also connect Rogers Fort Hill Park and Shedd Park with Lowell Cemetery and the city's cemeteries (City of Lowell 2018).

The attractions in Lowell that are open to the public as part of the LNHP are largely managed by NPS. The LNHP was established in 1978 and is operated by the NPS. It is a primary recreation attraction for the city of Lowell. According to the NPS Visitor Use Statistics website, the LNHP received around 481,536 visitors for the 2019 calendar year (NPS 2020). Opportunities available include museum exhibits, walking tours of the waterways, historic trolly rides, guided tours, music concerts, and boat tours on the Project canals.

The museum exhibits and activities are hands-on, interpretive, and educational opportunities. Key park experiences include the following:

Boott Cotton Mill Museum: Located in the Boott Cotton Mills Museum are interactive exhibits, a weave room, and video programs about the Industrial Revolution, labor, and the rise, fall, and rebirth of Lowell. This complex contains an adapted mill yard and is the most intact surviving example of the first phase of Lowell's mill construction. All four of the original 1835 mills in the Boott mill yard remain as part of an interconnected series of mill buildings.

Mill Girls and Immigrants Exhibit: The Mill Girls and Immigrants Exhibit is a self-guided tour through renovated boardinghouses displaying the kitchen, dining room, and bedrooms furnished in the style of the 1850s. Traditional museum exhibits are located on the second floor, including old photographs, newspaper articles, excerpts from letters, and highlights the lives of specific mill girls and immigrant workers.

Suffolk Mill Turbine Exhibit: This exhibit shows how water from the Western Canal flowed through an opening in the wall of a mill and fell on a large waterwheel in the basement to create kinetic energy. A guided tour also shows one restored turbine using a 13-foot drop of water to rotate shafts, gears, belts, and pulleys to a power loom.

Lowell National Historic Park Canal Walkways Tours: Self or professionally guided recreationists can follow walkways along the network of canals originating at the Pawtucket Dam and ending at the confluence of the Concord and Merrimack Rivers (NPS undated). Most of the walkways that follow the canals are also integrated into the common thoroughfares of the City of Lowell.

The Northern Canal Walkway: The Northern Canal Walkway provides interactive recreation with the historic structures of the Lowell Project, as well as a greenway along a scenic reach of the Merrimack River (NPS undated).

Boat tours led by NPS-guides also provide access to the Project impoundment. The canal boat tours highlight some of the Lowell Project facilities by travelling through the historic navigation locks (NPS undated). Additional recreational opportunities provided by NPS at the LNHP include trolley rides available for touring the city.

5.1.2 Vegetation and Waterborne Trash Management

Pursuant to the approved study plan, Boott reviewed several sources to summarize historical and current practices for vegetation and waterborne trash management in the Project Area.

Following establishment of the LNHP in 1978, MADCR[6], NPS, and Proprietors of the Locks and Canals (Proprietors), entered into an agreement in 1979 regarding management of the Lowell canal system. This agreement establishes MADCR as the lead party responsible for the maintenance of canal structural components, including canal banks and walls. As the lead party, MADCR was responsible for "landscaping and damage repair" to canal banks and walls, with assistance provided by NPS if needed. NPS was charged with the operation of the canal-related exhibits and services, and Proprietors were responsible for the operation and maintenance of the hydroelectric and hydromechanical parts of the Lowell canal system (NPS 1981). NPS developed and issued a Final General Management Plan (FGMP) in August 1981 to provide a basis for visitor use, resource management, and general development within the LNHP. The FGMP states management of the Lowell canal system will be accomplished through cooperative agreements between private and public entities, but MADCR is the lead agency responsible for maintaining, developing, and renovating the major elements of the canal system (NPS 1981).

In 1991, MADCR, the NPS, and Boott executed a Memorandum of Understanding (MOU) for the purpose of maintaining and operating the Lowell Canal System.[7] The MOU assigned specific responsibilities to each party and was filed with the Commission[8] on April 25, 1991 (MOU 1991). Article IV of the MOU directed NPS to assist MADCR in the removal and control of vegetation along the canal system, ("particularly that growing on and in the canal walls") and to assist MADCR in performing ground maintenance. Article IV also directed NPS to assist MADCR in the removal of litter and other waterborne trash from the Lowell Canal System, and states NPS is solely responsible for maintaining and cleaning, ("including removal of trash") all existing trash booms and safety lines/booms on the Lowell Canal System (MOU 1991).

Responsibilities assigned to MADCR under Article V of the MOU include serving as the lead agency for all grounds maintenance, keeping all grass, trees, and shrubs neatly trimmed and in a healthy condition, removing dead or diseased plants, fertilizing, pruning, and thinning of plants (as required), and approving ground maintenance or improvement plans as proposed by NPS. Article V also directs MADCR to assist NPS in

[6] The signatory of the 1979 agreement was the Massachusetts Department of Environmental Management (MADEM), the predecessor agency to MADCR.

[7] Proprietors of the Locks and Canals on the Merrimack River was included as a party in the MOU but did not execute the agreement.

[8] The 1991 Memorandum of Understanding is available on FERC's eLibrary (https://elibrary.ferc.gov/eLibrary/search) under docket number p-2790.

the removal and control of destructive vegetation along the canal system, and to cooperate with the NPS on developing a litter removal program for waterborne litter and trash on the canals. (MOU 1991). This article also directed MADCR to reimburse NPS for time and materials for work done on the canal system.

Article VI of the MOU directed NPS and MADCR to hold a joint annual meeting to develop an annual destructive vegetation clearing program and canal surface water cleanup program. The annual programs were to be developed in accordance with each agency's budget and seasonal staffing level. Under Article VI, MADCR was also directed to consult with NPS to develop a long-term capital improvement program for the canal system. The minutes of this annual meeting between MADCR and NPS were to be provided to Boott and the Proprietors each year (MOU 1991).

Article IX stated that the MOU would expire five years from the date of signing, with an option for renewal. Efforts to renew the MOU stalled in 1996, as MADCR issued a Grant of Easement[9] to the NPS in late 1995. This Grant of Easement provided NPS rights to implement construction and maintenance improvements at forty-two MADCR-owned parcels around the canal system. Such rights include landscaping, decking, and lighting. The Grant of Easement did not exclusively limit NPS's rights, only stating that construction and maintenance improvements must be consistent with the use of the area as a park. The Grant of Easement did not relinquish MADCR's waterborne trash and vegetation management responsibilities provided by the FGMP or MOU, as described above.

In the RMP for the Lowell/Great Brook Planning Unit, MADCR elaborates the agency was directed by the Commonwealth in 1993 to "concentrate on maximizing the riverfront component and minimizing, but not eliminating, [its] position in the downtown." Under a lower annual budget, MADCR states it has since focused its resources on the riverfront portion of the Lowell Heritage State Park system and less on the downtown canal system (MADCR 2014).

Through the current license term, FERC and Boott have corresponded on vegetation growth and waterborne trash accumulation at facilities within the Project boundary. The FERC Regional Office has regularly inspected the Project pursuant to its dam safety authority under Part 12 of the Commission's regulations. The most recent inspection of the Lowell Project performed on May 14, 2019 found that the facilities were in satisfactory condition, and there were no safety issues observed which required immediate attention. Following the inspection, FERC directed Boott to remove the vegetation and small tree growth observed at the crest of the Great River Wall and on the Hall Street Dam (FERC 2020; FERC 2019). A review of previous inspection reports indicate FERC found the Project facilities to be in overall good condition, and if necessary, directed Boott to remove vegetation growth or waterborne trash observed at Project structures. Boott typically identifies canal structures in need of vegetation removal and control in its Dam Safety Surveillance and Monitoring Reports annually

[9] The 1995 Grant of Easement is also generally referred to as LNHP Deed No. 40.

submitted to the FERC's New York Regional Office, and documents progress made during the preceding year.

Boott annually removes accumulated river-borne debris from the upstream side of the Northern Canal Gatehouse under an MADCR permit. This effort is performed as necessary, typically two to three times annually. Boott also removes debris that accumulates from the upstream side of the Guard Locks and Gatehouse in the Pawtucket Canal on an as necessary basis, both for aesthetics and to ensure that debris does not interfere with the proper functioning of the Guard Gates. Recently, Boott has agreed with the City of Lowell to conduct canal debris removal at recognized accumulation points, many of which are noted in this study.

According to documents and reports filed with the Commission, additional efforts to remove vegetation and waterborne trash from the Lowell canal system of have largely been independent or coordinated efforts between NPS, the City of Lowell, and Boott. In accordance with the MOU, NPS implemented frequent maintenance measures to limit trash accumulation and vegetation growth. On June 18, 2003, NPS filed their 2003 Lock Chamber Operations Manual with FERC. The manual states NPS employees should remove upstream trash in the vicinity of the lock chambers daily, and the lock chambers were to be flushed daily and cleaned of debris (NPS 2003). Operators were instructed to remove trash from in front of the following lock structures: Northern Lock at Pawtucket Gatehouse, Hydro Lock, Swamp Locks, and Francis Gate Lock (NPS 2003).

On October 26-27, 2006, Boott, the NPS, and the City of Lowell collaborated in a major effort to clean-up the canals and walkways The canals were drained for three days before workers from Boott, the City of Lowell, and LNHP could use heavy equipment to remove debris from within the canals. Volunteers also trimmed vegetation and picked up trash along the canal walkways (FERC 2007; Lowell Sun 2006).

After the Study Workshop, NPS provided a copy of their Exotic Species Treatment Calendar (dated September 11, 2018) prepared for the 2019 calendar year. The document presents the reported locations of target exotic vegetation species, methods for management, and an implementation calendar. The target exotic species were primarily reported at upland LNHP-structures outside of the Project boundary (Blacksmith Shop, Kerouac Park, Visitor Center Courtyard, Tremont Street Tracks, Kirk Street Headquarters, and Western Canal Walkway). At Project structures, NPS reported incidents of common invasive species including Garlic mustard (*Alliaria petiolata),* Asiatic bittersweet (*Celastrus orbiculatus*), Tree of Heaven (*Ailanthus altissima),* and Japanese knotweed (*Fallopia japonica*). Treatment methods employed by NPS include mechanical methods of hand-pulling, digging, cutting, seed-heading, mowing, and stump grinding, and chemical methods of foliar spray, herbicidal application to a cut stem/stump, basal bark, stem injection, and hand wicking (LNHP 2018).

There are also community efforts to manage the waterborne trash and vegetation growth. Local nonprofit groups including youth groups, Lowell Canalwaters Cleaners,

Coalition for a Better Acre, and Do-It-Yourself Lowell regularly host cleanup efforts during the warmer seasons.

Boott conducted visual surveys for vegetation growth and waterborne trash locations, and the results are provided below in Sections 5.5 and 5.6.

5.2 Field Inventory

As previously described, Boott conducted a field inventory to document existing non-Project recreation facilities within the Project's vicinity in the fall of 2019. Recreation sites inventoried included the Chelmsford Boat Access, Depot Street Boat Ramp, Greeley Boat Ramp, Lowell Heritage State Park, LNHP, Merrill Park, Merrimack Trail System, Moore's Falls Conservation Area, NPS Canal Walkway, Pawtucket Falls Overlook, and Rourke Brothers Boat Ramp. The Visitor Center (the only-FERC approved recreation facility), was closed on the days of inventory, but the external features (e.g. parking lot) were also inventoried.

Field inventory documentation, including a map of non-Project recreation facilities, representative photographs, and a description of amenities available at each facility is presented as Appendix B to this study report. The field inventory indicates there are considerable opportunities for recreation in the Project area. Most sites inventoried were reported in good condition, with parking lots, ample signage, and educational exhibits.

5.3 Visitor Use Data and Field Reconnaissance

In total, Boott conducted 53 personal interviews/visitor-intercept surveys between May 2019 and October 2019. In accordance with the approved study plan, Boott also collected field reconnaissance data during the personal interviews including estimating the number of vehicles, recreationists, and observed recreational activities. Results from the personal interviews are compiled in Appendix C and field reconnaissance data is summarized in Appendix D to this study report.

The online visitor use survey was made available to the public from June 2019 until June 2020. A total of 96 respondents completed the online survey. Results from the online surveys are compiled in Appendix E to this study report, and respondent zip codes with a representative map are compiled in Appendix F (for both the personal interviews and online surveys).

Of the personal interviews and online recreation surveys completed, the respondents thus far are typically regular visitors who visit three or more times per year (72 percent of personal interviewees and 76 percent of online respondents) and the remaining respondents identified themselves as first-time visitors or infrequent visitors. Personal interviewees travelled an average of 7.3 miles to the recreation area, with a range of 0.1 miles to 3,000 miles. Online respondents stated they travelled on average around 11 miles to the Project area. Most respondents stated they do not stay overnight in the

Project area in accommodations other than their primary residence (96 percent of personal interviewees and 90 percent of online respondents).

The most common recreational activities survey respondents participated in were trail-related activities (walking, dog-walking, hiking, running, or jogging), bank and/or boat fishing, and kayaking. Walking was the most common primary recreation activity. The majority (77 percent) of personal interview respondents rated their overall experience of recreational activities at the Project as “totally acceptable” or “acceptable.” The majority (92 percent) of personal interview respondents rated their overall experience of recreational activities at the Project as “totally acceptable” or “acceptable.”

According to respondents, the most frequently visited recreational facilities in the Project area were the Lowell Heritage State Park, the Rourke Brothers Boat Ramp, Chelmsford Boat Access, Merrimack Trail System, and LNHP-facilities. Participants were asked several questions regarding their general opinions of recreation in the vicinity of the Project, potential issues with the recreation facilities (i.e., crowding, safety), and recommendations for improvements to existing facilities. In general, the participants did not experience much crowding at the recreational facilities, parking issues, or lack of accessibility to the specific recreational facilities. Respondents both in-person and online tended to rate their overall experience at specific recreation facilities as “totally acceptable.” The most common recommendations for recreational enhancements were: (1) bathrooms/porta potty (2) improving/maintaining the existing structures such as the boat ramps, and (3) the addition of trash cans/trash control measures.

Field reconnaissance data obtained during personal interviews indicates the recreation facilities are well-utilized for many different activities. Walking (and dog-walking) and jogging/running were by far the most common activities observed by technicians. Additional common activities included bicycling, boating, picnicking, and fishing. The Merrimack Trail System and the Lowell Heritage State Park were highly utilized for many different recreational opportunities; these are connecting facilities, so it was common for recreationists to visit both. The Rourke Brothers Boat Ramp and the Chelmsford Boat Access were predictably mostly used for boating, but also commonly utilized for walking, dog-walking, fishing, and picnicking. The Chelmsford Boat Access adjoins a series of softball fields, and technicians reported softball tournaments with hundreds of attendees during the summer weekends. At all facilities, technicians generally reported less activity during the early daylight hours, and during rainy, cool times of the day.

5.4 Evaluation of Expanded Recreational Access in Project Canals

NPS and other stakeholders have expressed interest in new, different, and expanded recreational access to and within the Project canals. In accordance with the SPD, Boott consulted with the NPS, the City of Lowell, and other interested stakeholders to discuss various recreational opportunities associated with the Project canals. During the Study Workshop, stakeholders clarified they were looking for specific practical opportunities for

community on-water recreation. Boott and stakeholders' primary concerns were the recreational rights to the canal system and understanding public safety issues associated with providing recreational access in the Project's canal system.

In their FLA filed on April 30, 2021, Boott proposed to remove the four mill power stations (John Street Power Station, Bridge Street Power Station, Assets Power Station, and Hamilton Power Station) and associated canal infrastructure from the new FERC license. In the Commission's March 1, 2022 Determination on Requests, staff requested an analysis of the effects of Project operation on NPS boat tours and recreational rights, in relation to Boott's proposal to remove the majority of the canal system from the Project boundary. Boott provides that evaluation below in Section 5.4.1.

FERC also requested an evaluation of the potential for expanding public access to the canals for recreation (including NPS boat tours) in light of the results of the Operation Analysis of the Lowell Canal Study and in consideration of Project operation under normal and high flow conditions. Boott provides that evaluation below in Section 5.4.3 as it pertains to the downtown canal system (i.e. excluding the Northern Canal, which is addressed separately in Section 5.5.1.1).

5.4.1 Rights to Recreational Access to Project Canals

Boott reviewed many sources to understand the recreational rights to the Lowell canal system, including the MOU, the 1984 Great Deed between Proprietors and Boott (Proprietors 1984), the 1986 Order of Taking (Commonwealth of Massachusetts 1986), and the 1995 Grant of Easement from the Commonwealth of Massachusetts to the LNHP (Commonwealth 1995). These documents form the basis of the Resources, Ownership, Boundaries, and Land Rights Study filed with the Commission on November 1, 2021. The 1984 Great Deed details the sale of portions of the Project from the Proprietors to the current owner (Boott), and provides the metes, bounds, and elevations of all the structures conveyed, as well as associated easements, access and repair rights (Proprietors 1984). The 1986 Order of Taking details the take of properties, rights, and responsibilities from Boott to the Commonwealth, operating through MADCR (Commonwealth 1986). The 1995 Grant of Easement describes the properties and parcels that were leased from the Commonwealth to the NPS and the rights and responsibilities of both parties with respect to those properties and parcels (Commonwealth 1995).

The review of these documents indicates that the 1984 Great Deed conveyed all canals throughout the canal system to Boott, except for the Pawtucket Canal and the Lower Pawtucket Canal. Proprietors instead retained ownership of the Pawtucket Canal and Lower Pawtucket Canal, and granted Boott an easement for the right to operate the structures of these canals, to "install conduits, pipes, and wiring" and the right to maintain, repair, or replace the existing structures (Proprietors 1984).

By letter dated May 14, 1980, MADCR stated that they were currently in the process of negotiating purchase rights to the Lowell canal system which would allow for recreational boating in the canals, stating further that use of the canals and implementation of the boating program were key elements of the Lowell Heritage State Park (Massachusetts Department of Emergency Management [MADEM] 1980). Through the 1986 Order of Taking, MADCR purchased all air rights over the canals, including over the canal walls and dams, and the exclusive right to use water in the entire canal system for recreational, educational, and navigational purposes, unless said purposes interfere with Boott's hydroelectric generation (Commonwealth 1986). Included in the 1986 Order of Taking is a permanent and exclusive easement to MADCR for all canal walls, beds, or bottoms throughout the canal system for purposes consistent with the use of the canal system as a recreational park. These purposes specifically include placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature (Commonwealth 1986). The 1995 Grant of Easement from MADCR to LNHP did not convey these exclusive recreation rights to LNHP (Commonwealth 1995).

Based on the review of the MOU, the 1984 Great Deed between Proprietors and Boott, the 1986 Order of Taking, and the 1995 Grant of Easement from the Commonwealth of Massachusetts to the LNHP, Boott currently does not have any right to expand recreational opportunities throughout the Lowell canal system. MADCR purchased all recreational rights over all the canals and canal walls (even canals owned by Boott), including exclusive navigational rights such as boating or canoeing. MADCR maintains an exclusive and permanent easement throughout the entire canal system to install access points such as boat ramps, wharves, and docks. Boott and other stakeholders are not permitted to use the canals as recreational resources, as those rights are exclusively held by MADCR. Boott describes recreational rights and responsibilities in more detail in the Resources, Ownership, Boundaries, and Land Rights Study Report filed with FERC on November 1, 2021.

In the RMP for the Lowell/Great Brook Planning Unit, MADCR does reference its recreational rights over the Lowell canal system, but further elaborates the agency was directed in 1993 to minimize its position in the downtown area (MADCR 2014). On August 14, 2018, MADCR filed comments with FERC on the PAD and Scoping Document 1 for the Project. The comments discuss the various MADCR-owned properties, but do not reference their recreational rights to the Lowell canal system (MADCR 2018).

In their FLA filed on April 30, 2021, Boott proposed to remove the four mill power stations and associated canal infrastructure from the new FERC license. Boott also proposed to continue to manage the canal structures and water levels and flows, consistent with current agreements with the NPS and other stakeholders. Additionally, as reported in their November 15, 2021 Response to Additional Information Request filed with the Commission, Boott is proposing to maintain specific water levels throughout the downtown canal system as determined in consultation with NPS and other stakeholders.

As reported in detail in the Resources, Ownership, Boundaries, and Land Rights Study Report filed with the Commission on November 1, 2021, the 1995 Grant of Easement from MADCR to LNHP provides for specific recreational rights to structures of the downtown canal system including: Swamp Locks Gatehouse, Swamp Locks Dam (North), Swamp Locks Dam (South), Lower Locks Gatehouse, Lower Locks Lock Chamber, Lower Locks Dam, the Tremont Gatehouse, the Massachusetts Wasteway Gatehouse, the Rolling Dam Gatehouse (North), Rolling Dam Gatehouse (South), and the Hamilton Gatehouse. Although the rights to each structure vary, almost universally NPS was granted the rights at each structure to conduct land and canal tours, run interpretive programs, and the right to maintain, improve, and restore said structures. Additionally, through the 1995 Grant of Easement, MADCR conveyed to NPS easement rights at various structures and parcels adjacent to all the canals. These recreation and access rights at these structures and parcels exist independently of the owner of the structure, although it is worth noting that Boott is not known to have legal ownership of any structures of or within the Pawtucket Canal (where NPS boat tours currently operate). NPS does not currently run boat tours on the Western Canal, Eastern Canal, or Hamilton Canal, and Boott is not aware of any current interest to run boat tours on those canals. The primary structures of interest as it relates to current NPS boat tours in the downtown canal system (proposed to be removed from the Project boundary) are located on the Pawtucket Canal. NPS holds the rights to recreational access to these structures, as provided by the 1995 Grant of Easement, and these structures are jointly owned by MADCR and Proprietors.

Boott's proposal to remove the downtown canal system from the Project boundary will not affect NPS' recreational rights to conduct their boat tours. By way of the 1995 Grant of Easement with MADCR, NPS holds recreational rights to structures of the canals to operate their boat tours, run interpretive programs, and the right to maintain, improve, and restore said structures. This agreement exists independently of the Project license and the Commission's oversight. Boott does not hold recreational rights to the downtown canal system, and does not own structures of the Pawtucket Canal where NPS boat tours currently operate. As discussed in the in the November 1, 2021 Resources, Ownership, Boundaries, and Land Rights Study Report filed with the Commission, Boott does hold rights to flow water through the Pawtucket Canal. Boott is proposing to continue to manage the canal structures, water levels and flows using best practices, consistent with current agreements with the NPS and other stakeholders.

5.4.2 Public Safety of Recreational Access to Project Canals

Boott reviewed relevant safety and security requirements, guidance documents, and study reports, including the Project's approved Public Safety Plan (Boott 2020), FERC's Guidelines for Public Safety at Hydropower Projects (FERC 2011), Recreation Development at Licensed Hydropower Projects (FERC 1996a), and the Security Program for Hydropower Projects (FERC 2016). Boott also reviewed pertinent guidance, design, and planning documents relating to recreational access throughout the canal system.

In accordance with the Commission's approved Public Safety Plan for the Project, Boott maintains fences and gates, lights, sirens, and warning signs to protect the public from the hazards of Project operations (Boott 2020). Boott has historically worked with FERC to strengthen the Public Safety Plan and allow access only where appropriate and safe. As described above, Boott does not have recreational or navigational rights to the canal system. Further, because of the steep canal walls, dams, historic locks and gate structures, and intake/outlet structures associated with the Project, Boott maintains that such access presents an unacceptable risk to public safety and Project security. In the 1990s, incidents of accidental drownings/body recoveries throughout the canal system triggered Boott and FERC to update the Public Safety Plan, install additional warning signs, and fencing to enhance public safety (Boott 1991; FERC 1996b; Boott 1998; Boott 2000).

While Boott does not have recreational or navigational rights to the canal system, Boott believes that providing access would present a number of significant safety concerns. As an example, FERC's Guidelines for Public Safety at Hydropower Projects states that canals create hazardous conditions due to the steep sides and hard surfaces. The safety guidelines indicate water, algae, and mud make conditions too slick and dangerous for recreationists to escape or be rescued. The multiple dams located throughout the canal system (Swamp Locks Dam, Lower Locks and Dam, Lawrence Dam, Hall Street Dam, Merrimack Dam, Rolling Dam, and Boott Dam) as well as the many gates and lock structures, are all also considered potentially hazardous (Figure 3-2). Such structures can create unexpected dangers as surface waters appear calm, but undercurrents are unpredictable. Powerhouse intake areas throughout the canal system also pose hazards to recreationists as currents can change unexpectedly. Boaters will often want to go over lower dams or explore restricted areas, but this must be discouraged by warning signs and barrier systems. As stated in FERC's guidelines, allowing recreationists access to or near to Project facilities poses significant safety and security risks.

In accordance with the SPD, Boott researched infrastructure enhancement that may be required to provide safe public access to the canal system and how such improvements may affect aesthetic and historic resources. FERC recommends that access points, such as canoe/kayak or boat ramps, should be at least 300 feet away from any structure that may pose a hazard (such as dams, intakes, and gate structures). A system of warning devices such as signs, boat restraining barriers, sirens, and buoys also may need installation at least 300 feet from any hazardous structure. At a minimum, escape devices such as life preservers and safety ropes are recommended to be installed near dams, canals, and any other hazardous structures, although FERC acknowledges theft and vandalism can be an issue with such installations. Permanent escape ladders may be considered (especially for canals) and should be installed every 250 feet on either side, but these devices are "attractive nuisances" and can often exacerbate unsafe conditions. Boaters will need escape ladders or other similar emergency escape points as situations can turn dangerous, such as unexpected lightning storms. Any provision of public access to the canals would necessarily create additional responsibilities for city, state and NPS public safety and law enforcement authorities. Additionally, information on dangerous areas, restrictions on speed, direction, or access (especially in canals),

alcohol use restrictions, enforcement and penalties, and other information relevant to safe recreational practice should be provided to recreationists at access points (FERC 2011).

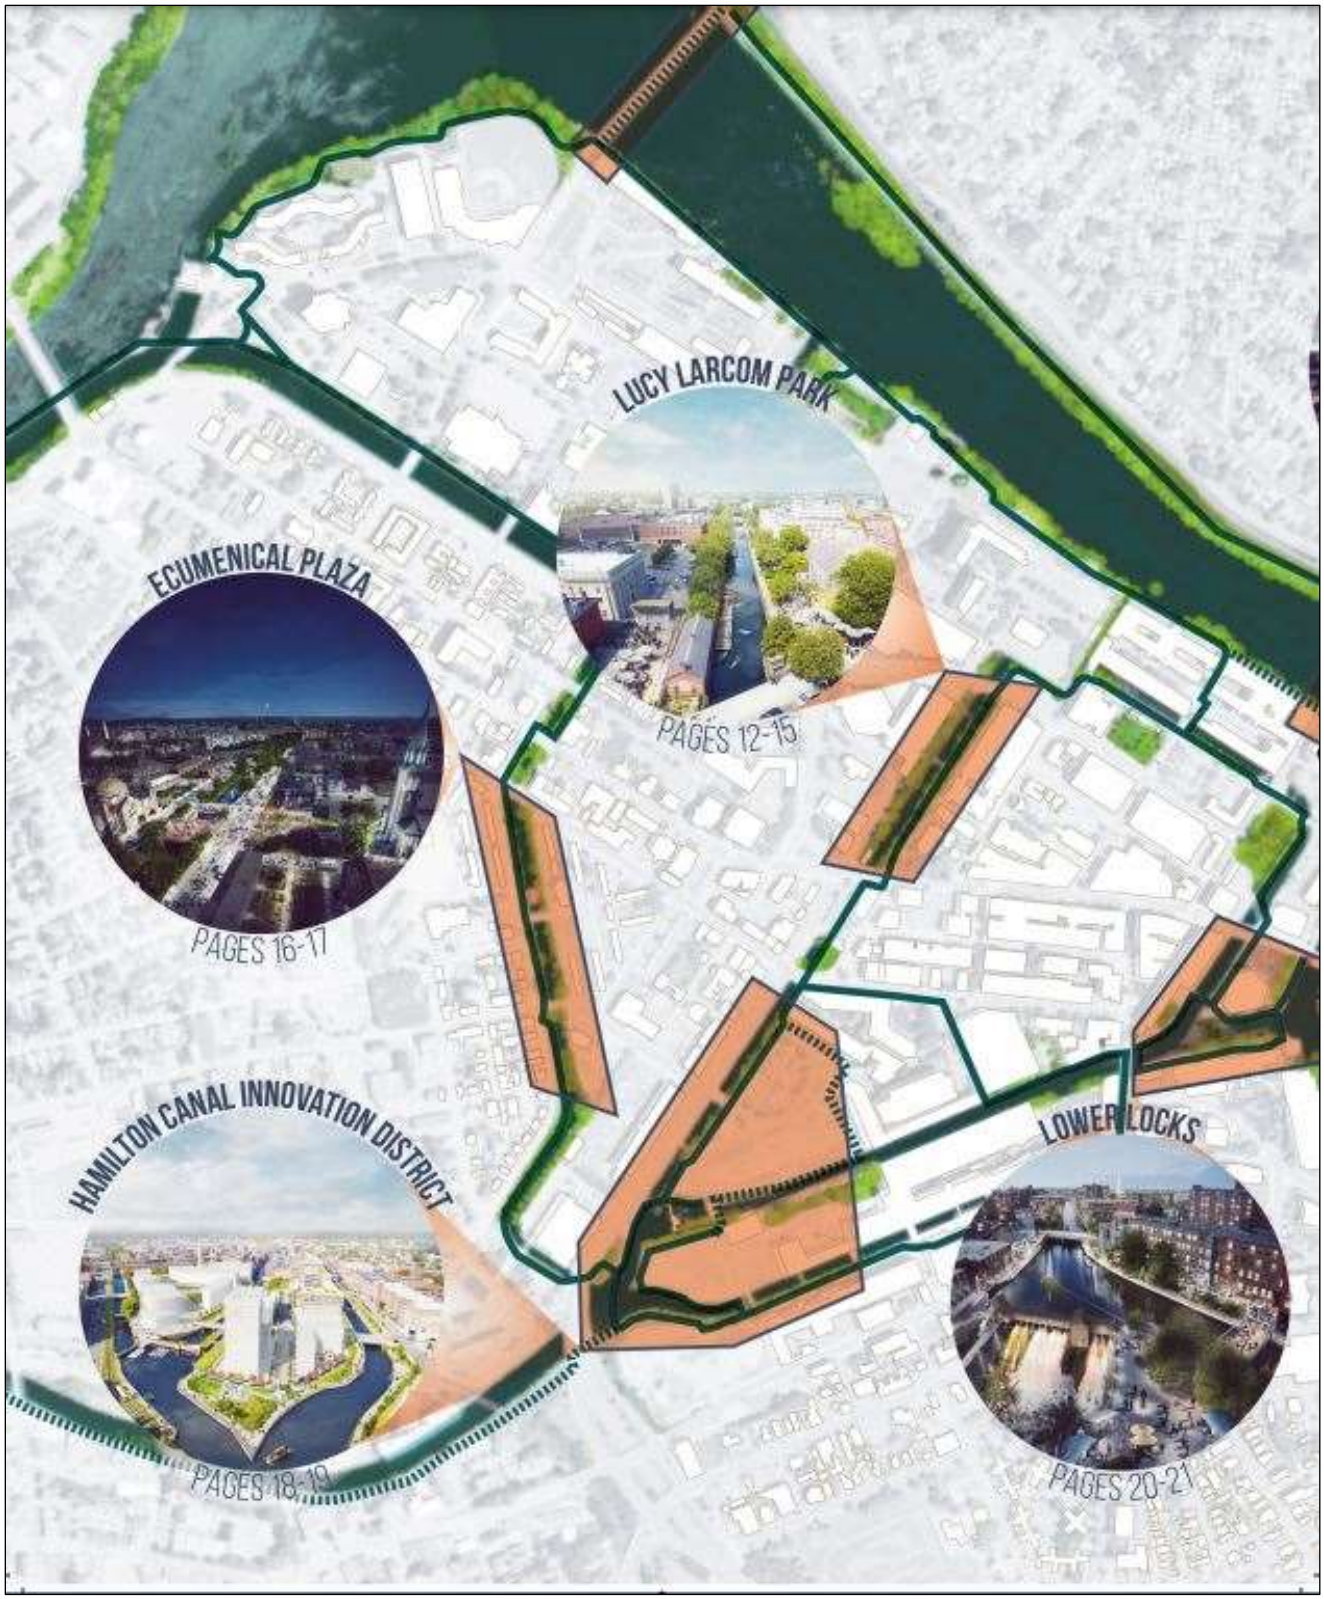
5.4.3 Expansion of Recreational Access to Project Canals

Given the information presented in Section 5.4.1 and 5.4.2, the opportunities for expansion of recreational opportunities in the Project canals are limited. MADCR exclusively owns all rights to allow recreation on or in the Project canals and holds easement rights to install recreational access points. As such, Boott does not have the rights to provide expanded recreational opportunities within the canal system. Surface water recreation in the canals was evaluated by the Lowell Historic Preservation Commission and the LNHP in public planning documents such as the 1977 Brown Book, the 1981 FGMP, and the 2017 Lowell Waterways Vitality Initiative Action Plan (Action Plan). The LNHP 1990 Preservation Plan Amendment stated:

> "The canals offer few boating opportunities beyond the Park's well-organized tour boat program. Because of swift water, lack of depth and width, low clearances, and other physical restrictions, water recreation is limited. If pleasure boating by individuals is to be considered, it should be kept to the Pawtucket Canal, and allowed mainly as a link to the Merrimack River. Paddle boating is possible if access, safety, and permitting are addressed. The Merrimack Canal at Lucy Larcom Park has been identified as the best place for still water activities such as this. In general, water taxis, dinner boats, and other organized boating program's will be encouraged, subject to permission from the Heritage State Park [MADCR] which controls recreational boating rights on the canals. The Pawtucket and Northern Canals offer possible routes, and could become a feature of the Canalway through private concessions."

The 2017 Action Plan was published as a collaborative report from the City of Lowell, the Lowell Heritage Partnership, and ex-officio members from the LNHP. The report presented consensus from the group on certain water-related areas that offer the best potential. The Action Plan identified the following canal areas: Lucy Larcom Park (Merrimack Canal); Ecumenical Plaza (Western Canal); Lower Locks, and the Hamilton Canal Innovation District (Hamilton, Pawtucket, and Merrimack Canals). The areas identified are shown in Figure 5-2.

Figure 5-2. Water-Based Areas Identified in the 2017 Action Plan



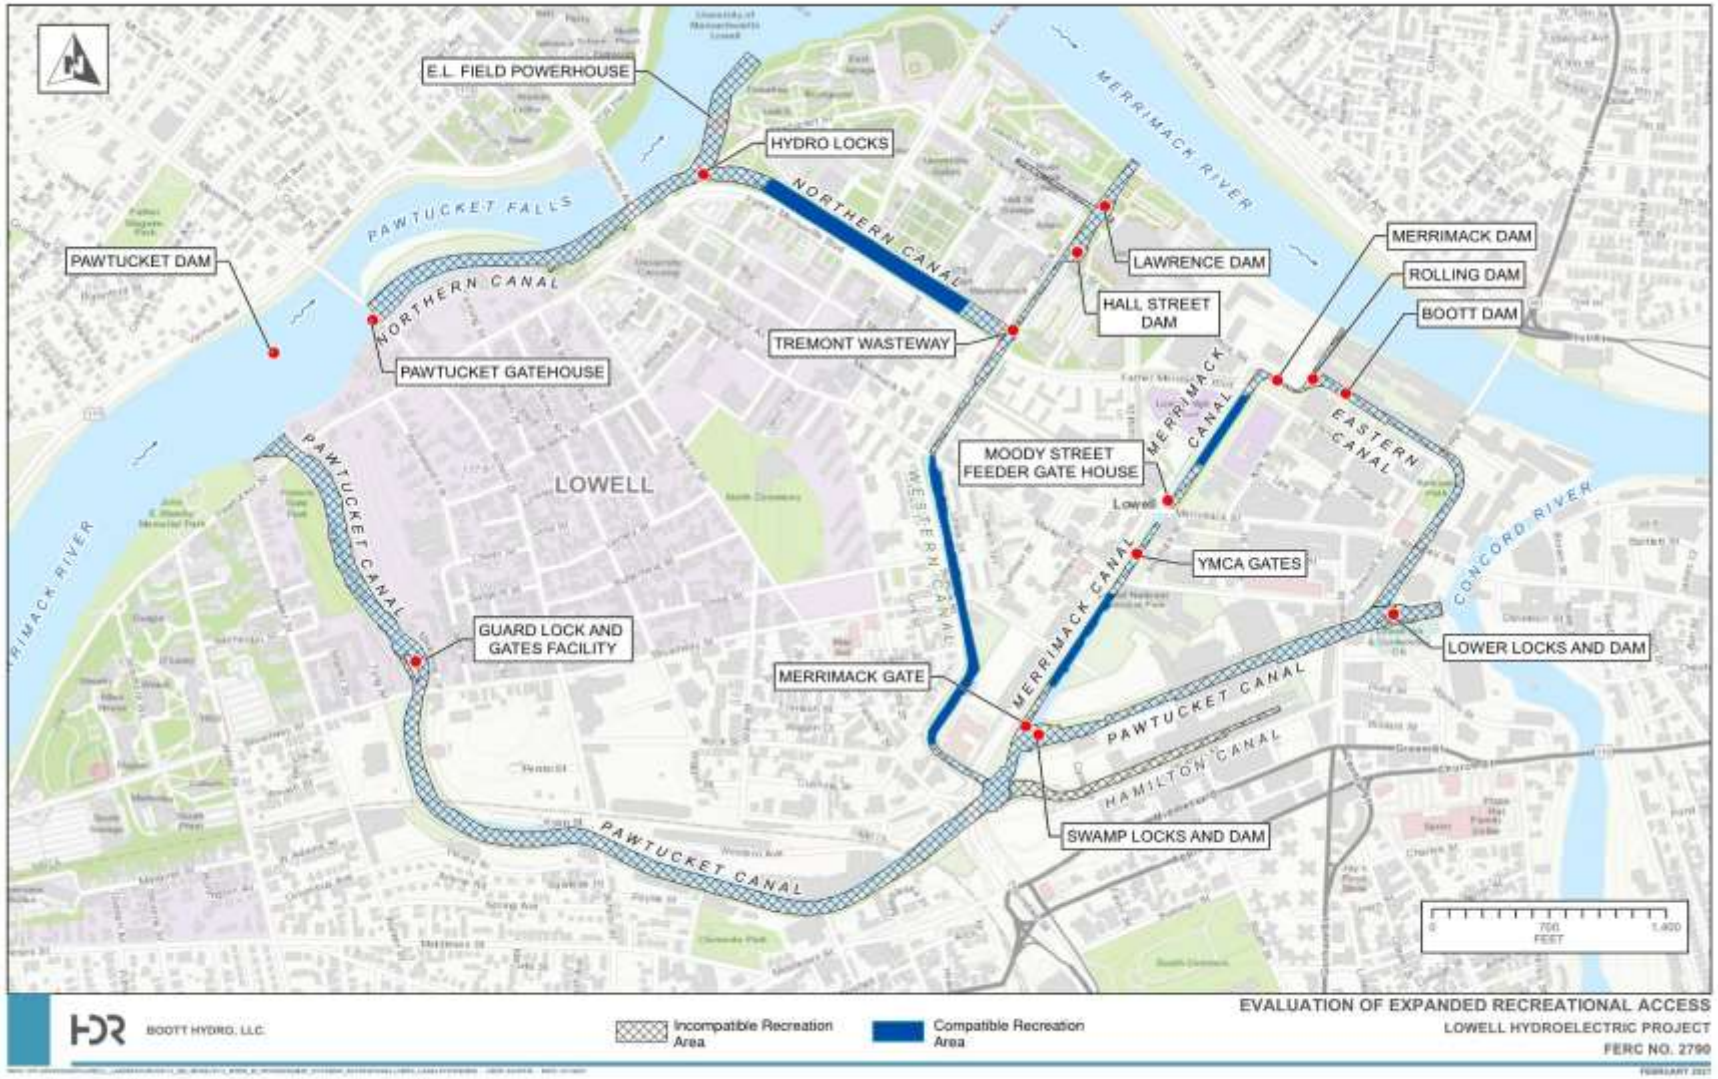
In their March 1, 2022 Determination on Requests, FERC recommended an evaluation of the potential for expanding access to the canals for recreation (including NPS boat tours) in light of the results of the Operation Analysis of the Lowell Canal Study and in consideration of Project operation under normal and high flow conditions. Boott provides that evaluation here as it pertains to the downtown canal system (i.e. excluding the Northern Canal, which is addressed separately in Section 5.5.1.1).

On February 25, 2021, Boott filed with the Commission their Operation Analysis of the Lowell Canal Study. This report determined that the four downtown power stations were only operated 34 percent of days during the total period of record studied (January 1, 1998 – December 31, 2007). This is primarily due to the fact that Boott operates the Project to maximize flow through the available units at the E.L. Field Powerhouse, then routes any additional flows through the Pawtucket Canal system. The E.L. Field turbine-generator units are more efficient and operate at a higher head than the older canal units and are, therefore, the priority first-on, last-off units in the Project operations scheme. When river flows exceed the hydraulic capacity of the E.L. Field units (approximately 3,300 cubic feet-per-second [cfs] per unit or 6,600 cfs for both units), excess flows up to approximately 2,000 cfs are routed through the Guard Locks Complex into the downtown canal system and to the canal units. Any flows in excess of approximately 8,600 cfs (6,600 cfs at E.L. Field plus 2,000 cfs via canals) are passed over the Pawtucket Dam spillway.

The study found that during normal flow conditions, including the peak recreation season (May through October), Boott historically only operated the downtown units approximately 25 percent of the time. During higher flow conditions above 6,600 cfs, Boott would typically divert up to 2,000 cfs past the Guard Locks Complex to the canal units. Overall during the period of record, the four downtown power stations were only operated 34 percent of the time.

With recreational rights, Project operations and public safety, and prior scoping by stakeholders in mind, Boott has identified specific segments of the canal system as potentially compatible with public access for recreation, and those areas are shown below in Figure 5-3. This evaluation does not include the already-established NPS tour boat program. The Merrimack Canal along Lucy Larcom Park is a recreation area potentially compatible with public access for recreation. Surface water recreation should be restricted to the area in between the Moody Street Feeder Gatehouse and the Merrimack Dam, at least 300 feet from either structure. This area is acceptable for stillwater activities like paddle boating, as identified in the 1990 Preservation Plan Amendment. The portion of the Merrimack Canal downstream from Merrimack Gate is potentially compatible for similar surface water recreation, and this area was identified in the 2017 Action Plan as a part of the Hamilton Canal Innovation District. The segment of Western Canal along the Ecumenical Plaza area has also been identified as potentially compatible with stillwater recreation. The segment of the Northern Canal between Hydro Locks and Tremont Gatehouse could also be compatible with stillwater recreation.

Figure 5-3. Potentially Compatible and Incompatible Recreation Areas



The remaining portions of canal system, including the remaining portion of the Hamilton Canal Innovation District (Pawtucket Canal, Hamilton Canal, and Swamp Locks) and the Lower Locks area, are not considered compatible due to public safety concerns, water levels and flows, and property rights. This is consistent with prior evaluations of on water recreation in the canals, with the 1977 Brown Book stating “the canals offer few boating opportunities beyond the Park's well-organized tour boat program. Because of swift water, lack of depth and width, low clearances, and other physical restrictions, water recreation is limited.” These areas identified by Boott may have swift currents and hazardous structures through the canals, including intakes, dams, locks, gate structures, and low-clearance bridges. Boott intends to retain current public safety signage throughout the canal system in accordance with the existing Public Safety Plan, such as the signage at Swamp Locks and Lower Locks stating, “Beware Water Rises Rapidly.” In addition to being unsafe, Hamilton Canal and the Lower Pawtucket Canal below Swamp Locks are both flanked with tall, renovated mill buildings on either side which severely limit emergency access and the ability to construct safety devices. Notably, Boott does not own the Pawtucket Canal, Swamp Locks, or Lower Locks; these structures remain under the ownership of Proprietors.

The Operation Analysis of the Lowell Canal Study indicates that Boott historically did not typically operate the downtown units during peak recreation season due to lack of high flows during the summer months. Therefore, it is Boott’s understanding that their proposal to remove the majority of the downtown canal system from the Project boundary does not change the limited recreation expansion options available in the downtown canal system, as presented above. As proposed in the FLA, Boott will continue to manage the canal structures, water levels and flows using best practices and consistent with current agreements with the NPS and other stakeholders. Boott does not have any right to expand recreational access in the Project canals regardless of the removal of the four downtown mill power stations from the Project boundary; MADCR holds those recreational rights, and public safety hazards will remain due to the fact that Boott will maintain current flows and water levels as agreed upon with NPS and other stakeholders.

As noted, FERC also requested an evaluation of the potential for expanding access to the canals for NPS boat tours in the downtown canal system light of the results of Operation Analysis of the Lowell Canal Study. The Operation Analysis of the Lowell Canal Study does not provide any new information to inform expansion of NPS boat tours in the downtown canal system. Recent conversations with NPS indicate their boat tours on the Pawtucket Canal are not notably affected by canal flows or Project operations as long as water levels are maintained within specified limits. As discussed below in Section 5.5.1, NPS historically operated boat tours on the Pawtucket Canal and the Northern Canal, and NPS currently operates boat tours on the Pawtucket Canal. Based on recent consultation with NPS, there is limited to no interest currently in expanding the boat tours to the Western and Eastern Canals due to low-lying bridges and other obstructions. To NPS’ knowledge, the Western Canal has never been successfully navigated, and to date Boott is not aware of any desire to navigate the

Western Canal as part of the NPS boat tour program. The Eastern Canal and the connecting Merrimack Canal in particular were never deemed suitable by the NPS for boat tours according to early public planning documents. Although Boott does not consider navigation of the Hamilton Canal safe due to reasons mentioned above, that decision is left to the discretion of NPS and MADCR, as they hold the recreational rights. Boott and/or Project operations do not currently prevent NPS from conducting boat tours on the Western Canal, Eastern Canal, or Merrimack Canal, and Boott's future management of the canal system will also not prevent such expansion of NPS boat tours. Based on recent consultation with NPS, NPS' main goal with the expansion of boat tours is to regain use of the Northern Canal as part of their regular boat tours (this is addressed separately below in Section 5.5.1.1).

Boott notes that the information presented above is developed at a conceptual/screening level only for purposes of this report. The feasibility of any potential safety, security, and recreation development activities is subject to additional design, permitting, and other federal, state, and local municipal requirements as may be appropriate. Further, this information is not intended to serve as a proposal by Boott for any recreation enhancements and should not be construed as such.

5.5 Evaluation of Water Levels and Flows on Recreational Access

In accordance with the SPD, Boott initiated data collection to better understand effects of the crest gate and water levels and flows on (1) NPS boat tours and (2) access to the Northern Canal Walkway.

In their letter dated March 1, 2022, the Commission requested a description of boat tour routes used by NPS (past or present) within the Northern and Pawtucket Canal system, including a description of locks or other navigational features that the tours pass through. Boott provides that information below in Section 5.5.1. FERC also requested an evaluation of the effects of Project operation on NPS boat tours in the Northern Canal. Boott provides that analysis below in Section 5.5.1.1.

FERC requested an evaluation of the effects of Project operation on current NPS boat tours, in relation to Boott's proposal to remove the majority of the canal system from the Project boundary. Boott provides this evaluation as it relates to the Northern Canal in Section 5.5.1.1, and as it relates to the Pawtucket Canal in Section 5.5.1.2.

FERC also requested an evaluation of the potential for expanding NPS boat tours in light of the results of the Operation Analysis of the Lowell Canal Study and "in consideration of Project operation under normal and high flow conditions (including an assessment of surge gate and shut down options)." Given that use of the surge gate/shut down options only pertain to NPS boat tours on the Northern Canal, this is addressed below in Section 5.5.1.1.

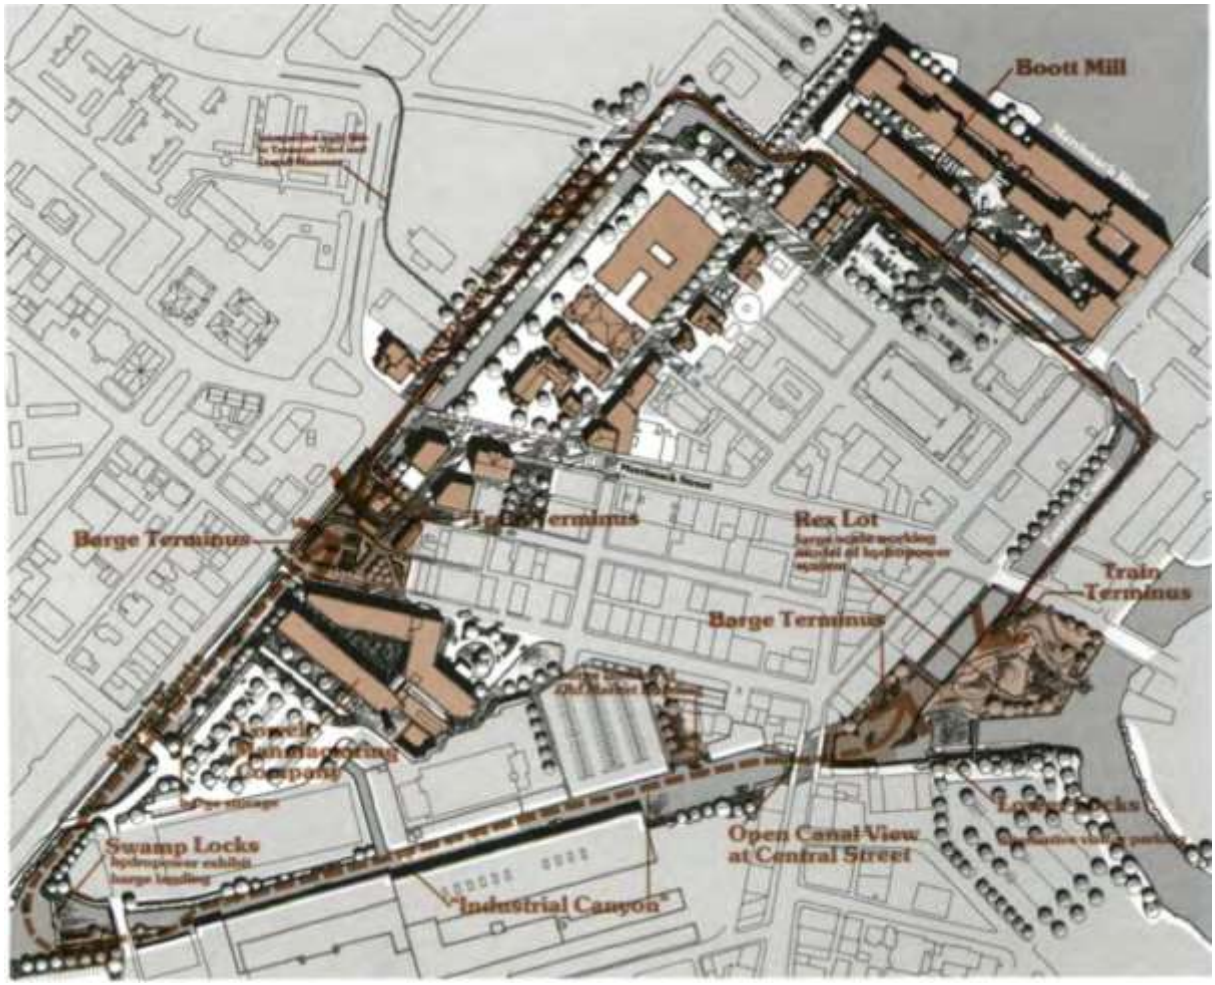
Lastly, FERC also recommended the Recreation and Aesthetics Study Report identify the number of days that the Northern Canal Walkway would need to be closed

seasonally due to flows resulting from Project operation, and this is provided in Section 5.5.2.

5.5.1 Historical and Current NPS Boat Tours

The 1977 Brown Book introduced the concept of combined train and boat tours throughout and around the canal system as a major attraction of the LNHP. The Downtown Canal Loop was designed as two segments: a boat tour to the south and a train to the north (Figure 5-4). Starting at the LNHP Visitor Center on the Merrimack Canal, the visitors could travel by boat through the Merrimack Canal to Swamp Locks on the Lower Pawtucket Canal, and descend down through the Swamp Locks Lock Chamber into the area known as the Industrial Canyon. The terminus to this boat tour was located on the Eastern Canal past the confluence with Lower Locks. Along this route, visitors would be allowed to disembark for a closer look at the Swamp Locks and Lower Lock Complexes, or walk among scale models of the mills and operate control devices on the canals. The visitor could then continue the Downtown Canal Loop by train around the Eastern Canal bends, Boott Mill, and the Merrimack Canal, ending back at the LNHP Visitor's Center.

Figure 5-4. 1977 Brown Book Downtown Canal Loop



As presented in the 1977 Brown Book, the Outlying Canal Loop was also designed to take off from the LNHP Visitor Center on the Merrimack Canal and proceed north up the Pawtucket Canal (Figure 5-5). The tour would utilize the Guard Locks Lock Chamber to complete the tour north through the Pawtucket Canal and enter the Merrimack River. The tour would continue through the Pawtucket Gatehouse utilizing the lock structure into the Northern Canal. Proceeding down the Northern Canal, the visitor would pass by the Northern Canal Wastegate House and the Northern Canal Walkway. The designed route continues along the Northern Canal and Western Canal (where there are no lock structures), before returning to the LNHP Visitor Center.

Figure 5-5. 1977 Brown Book Outlying Canal Loop

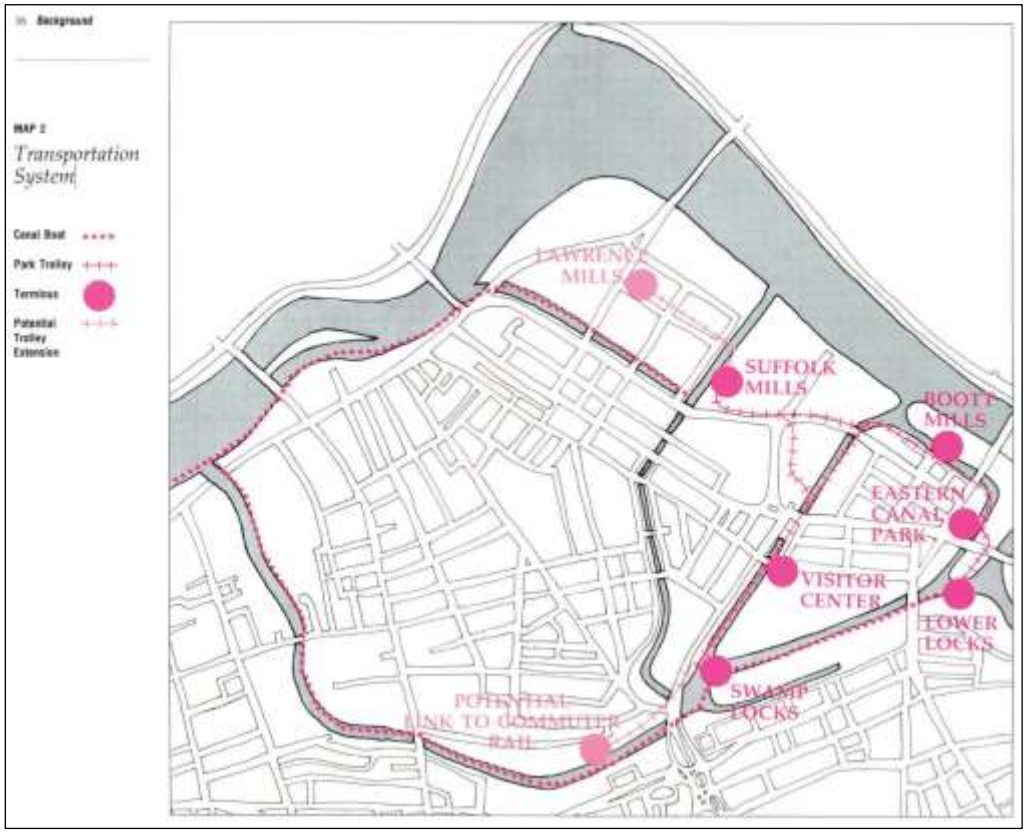
During the licensing of the Project, the Licensee reported that the lock at the Pawtucket Gatehouse had not been used since 1871 and was blocked by a concrete wall built in 1939. Additionally, the Licensee was in consultation with historic preservation and recreation officials regarding the Project's balance with NPS boat tours and other recreational boating. At the time, the plans for boat tours and recreational boating on the canals were hindered by low bridges on the Western Canal and the inland section of the Northern Canal. Long-range planning for boat traffic through the entire length of the Pawtucket Canal, from the Merrimack River to the Concord River, was also hindered by a bridge problem. However, the installation of Hydro Locks during the construction of the Lowell Hydroelectric Project meant the flows of the Northern Canal could be hydraulicly separated from remainder of the canal system, allowing for the maintenance of lower water levels in the downtown canal system during the boating season, thus allowing for clearance under low-lying bridges (Boott 1980).

As noted above in Section 5.4, by letter dated May 14, 1980, MADCR stated that they were in the process of negotiating purchase rights to the Lowell canal system which

would allow for recreational boating in the canals (MADEM 1980). Through the 1986 Order of Taking, MADCR purchased all air rights over the canals, including over the canal walls and dams, and the exclusive right to use water in the entire canal system for recreational, educational, and navigational purposes (Commonwealth 1986). Included in the 1986 Order of Taking is a permanent and exclusive easement to MADCR for all canal walls, beds, or bottoms throughout the canal system for purposes consistent with the use of the canal system as a recreational park. These purposes specifically include placement and attachment of docks, wharves, walls, and boat ramps of a temporary or permanent nature (Commonwealth 1986).

As reported in the 1990 Preservation Plan Amendment, the acquisition of these rights to MADCR allowed for the significant restorations of lock structures at Lower Locks, Guard Locks, and the Pawtucket Canal. Between the advent of the LNHP and the 1986 Order of Taking, boat tour operations were very limited due to the recreational rights issue as well as the infrastructure improvements and physical obstructions noted above. The 1990 Preservation Plan Amendment provided an updated layout of the combined canal boat tours and train system, showing the tour boats proceeding through the Pawtucket Canal and Lower Pawtucket Canal and the Northern Canal. The plans for full passage through the Western and Merrimack Canals were deemed infeasible due to overhead obstructions (e.g. bridges) that blocked passage, and it was noted that Swamp Locks Lock Chamber was inoperable but under repair by MADCR (Figure 5-6).

Figure 5-6. 1990 Preservation Plan Amendment Canal Boat Route



On April 14, 2022, Boott held a conference call with NPS to obtain information on their historical and current canal boat tour operations. The information discovered through this literature review is consistent with NPS operations staff's understanding of historical boat operations during this time frame. NPS states they do not ever recall successful navigation on the Western Canal (as originally conceived), and infrequent use, if any, of the Merrimack Canal for boat tours. As reported by NPS, between the late 1980s through 1994, NPS boat tours would run in either direction from Swamp Locks up through Guard Locks Locking Gatehouse (Guard Locks Complex), continuing north onto the Merrimack River and through the Pawtucket Gatehouse, using the Pawtucket Gatehouse Lock Chamber to enter onto the Northern Canal. Navigation on the Northern Canal continued through Hydro Locks to the Aiken Street dock before turning around to loop back to Swamp Locks. NPS staff would usually end the tour at Swamp Locks, or lock down Swamp Locks to the Lower Locks Complex. NPS staff report they usually did not lock down Lower Locks to access the Concord River.

NPS staff report the full loop of this tour was 1-2 hours and could be performed up to six times a day. There was usually interpretation at the Guard Locks Complex and the Pawtucket Gatehouse, and visitors could disembark to explore these features. In all, these tours spent about a full hour on the canals, and another hour at interpretations and other stops. NPS staff noted that there were no stops on the Northern Canal from the

Pawtucket Gatehouse to the Aiken Street dock; approximately ten minutes were spent navigating from Hydro Locks to the Aiken Street dock and back, and another fifteen minutes from Hydro Locks to the Pawtucket Gatehouse. About up to half an hour was spent navigating on the Northern Canal in total per tour.

Following the partial failure of the bayboard section of the Great River Wall in 1994 (Enel Green Power North America [Enel] 2008), NPS ceased boat tour operations on the Northern Canal, as discussed more below in Section 5.5.1.1. With the installation of the surge gate in 1999, and the safety threshold of 3,500 cfs established, NPS could resume canal boat tour operations on the Northern Canal. However, complications with Hydro Locks between 1996-1997 made the locking mechanisms inoperable, and NPS has not resumed regular boat tour operations on the Northern Canal, but will navigate the Northern Canal on specific occasions.

Currently, the NPS boat tour season lasts from May 15 through October 15. NPS reports that for the last 10-12 years they have offered up to four boat tours a day, during the boating season, touring up and down the Pawtucket and Lower Pawtucket Canal. Essentially, they launch at Swamp Locks, locking down using the Swamp Locks Lock Chamber, navigating to the Lower Locks Complex, turning around and locking back up through the Swamp Locks Lock Chamber and the Guard Locks Locking Gatehouse, and turning around at the confluence of the canal with the Merrimack River. The tour continues back down the Pawtucket Canal, locking down at the Guard Locks Locking Gatehouse and ending at the Swamp Locks Complex. Depending on whether they are locking up or down, NPS will allow boaters to disembark to view the complexes. NPS does not currently dock at or lock up/down at Lower Locks due to safety concerns.

5.5.1.1 Evaluation of Effects of Project Operations on NPS Boat Tours on the Northern Canal

In their letter dated March 1, 2022, the Commission recommended (1) an evaluation of the effects of Project operation on NPS boat tours in the Northern Canal; (2) an evaluation of the effects of Project operation on NPS boat tours, in relation to Boott's proposal to remove the majority of the canal system from the Project boundary; and (3) an evaluation of the potential for expanding access to the canals for recreation (including NPS boat tours) in light of the results of the Operation Analysis of the Lowell Canal Study and in consideration of Project operation under normal and high flow conditions (including an assessment of surge gate and shut down options). Boott provides those evaluations here as they pertain to the NPS boat tours on the Northern Canal.

As noted above, NPS operated boat tours on the Northern Canal from the late 1980s to 1994, spending up to a half hour per tour navigating the Northern Canal from the Pawtucket Gatehouse, turning around at the Aiken Street dock, and navigating back through Hydro Locks to the Pawtucket Gatehouse. In 1994 NPS ceased boat tours on the Northern Canal after overtopping and failure of the bayboard section of the Great River Wall. The FERC New York Regional Office expressed their concerns by letter to the NPS on March 31, 1994, recommending that NPS discontinue both the Northern

Canal boat tours and walking along the Northern Canal Walkway until further studies were conducted (FERC 1994; Enel 2008). In their September 1994 Environmental Inspection Report, FERC stated "*the existence of a boat tour in a power canal is a practice that normally would be discouraged. Aside from the obvious hazards associated with power production it can also present unforeseen dangers. The Project, however, was designed with the idea that tour boats would operate in the canal. Recent events seem to indicate that this practice be revisited in terms of public safety*" (FERC 1994).

In 1999, Boott completed construction and testing of the surge gate. The surge gate is designed to automatically open when the E.L. Field station is tripped off-line, which prevents overtopping of the Great River Wall and prevents flooding of the historic Pawtucket Gatehouse and Northern Canal Waste Gatehouse. Testing of the surge gate indicated the gate successfully attenuated the resulting transient wave that can occur in the Northern Canal during sudden plant shutdown. However, testing posed the safety concern that should the station trip off-line while the NPS is operating tour boats on the Northern Canal, the boat and passengers could be drawn through the open surge gate (Enel 2008; FERC 2000). Testing demonstrated that the transient wave produced on unit trip was not large enough to overtop the Great River Wall when Northern Canal flows are less than 3,500 cfs (e.g., operating the E.L Field at half-capacity) and so the surge gate may be temporarily deactivated under such conditions. Thus, NPS and Boott agreed that boat tour operations can occur on the Northern Canal only if the Merrimack River flow is less than 3,500 cfs and if the surge gate is locked out/tagged out to prevent automatic opening (Enel 2008; FERC 2000). At Merrimack River flows as low as 3,500 cfs, flows in the Merrimack River are effectively equal to flows in the Northern Canal.

In a letter addressed to NPS and dated June 1, 1999,[10] FERC stated "*while this office conceptually disagrees with allowing recreational vessels in a power canal, the license stipulates the use of the canal for this purpose*." FERC indicated in this letter the agreed-upon protocol between NPS and Boott for tour boat operation on the Northern Canal was satisfactory. This letter from FERC also indicates a May 6, 1999 conference call in which NPS and Boott outlined the agreement to FERC.

The 1999 testing of the surge gate indicated it may only be deactivated (i.e. locked-out/tagged-out) if Merrimack River flows are less than 3,500 cfs. This lock-out/tag-out procedure is jointly undertaken by Boott and NPS personnel (Enel 2008; FERC 2000). When flows in the Merrimack River (and consequently the Northern Canal) are above 3,500 cfs and the surge gate is deactivated to prevent automatic opening, there is risk of overtopping of the Great River Wall, flooding of the Pawtucket Gatehouse and Northern Canal Waste Gatehouse, and undermining and/or weakening of the gatehouse and portions of the Northern Canal. If persons are boating on the Northern Canal, there is risk to human life in that passengers could be drawn through the open surge gate.

[10] Ascension Number 19990614-0512

Accordingly, the 3,500 cfs threshold for boating on the Northern Canal was agreed upon between Boott and NPS, and approved by FERC in 1999.

As discussed above, in recent years NPS holds boat tours on the Northern Canal only on special occasions mostly due to the locking issues at Hydro Locks that arose around 1996. NPS staff recently report that Hydro Locks is inoperable as pins were bent as they were frozen in at one point. Based on drawings these pins may be the hinge pins or the pins that lock the gates together in the closed position. The pins can no longer be moved or removed. Since they were frozen, they do not lock tight enough and there is leakage. Additionally, NPS reports that Hydro Locks is mired in mud (NPS 2018). As reported to FERC in their March 31, 2022 Response to Additional Information Request, Boott intends to install a downstream fish exclusion system including a new trashrack structure in the E.L. Field powerhouse forebay. During the installation of the downstream fish exclusion system, the Northern Canal will be dewatered, providing Boott the opportunity to inspect and repair as needed Hydro Locks and its locking mechanisms, as well as to determine whether the Hydro Locks gates are mired in mud.

In their March 1, 2022 Determination on Requests, FERC requested an evaluation of the effects of Project operation on current NPS boat tours, in relation to Boott's proposal to remove the majority of the canal system from the Project boundary. The majority of the Northern Canal, i.e., the section between the Northern Canal Gatehouse and Hydro Locks, will remain within the Project boundary. However, the section of the Northern Canal between Hydro Locks and the Western Canal is proposed to be removed from the Project boundary. Boott does not anticipate the removal of this section of the Northern Canal from the Project boundary will affect NPS boat tours. In their FLA filed on April 30, 2021, Boott proposed to continue to manage the canal structures and water levels and flows using best practices, consistent with current agreements with the NPS and other stakeholders. Given Boott's canal elevation agreement with NPS, Boott regularly coordinates on water elevations with the NPS and other stakeholders. As reported in their November 1, 2021 Response to Additional Information Request, Boott is proposing to maintain specific water levels throughout the canal system as determined in consultation with NPS. The target water level for this portion of the Northern Canal is 86.7 ft NGVD 29.

Lastly, in their March 1, 2022 Determination on Requests, FERC requested an evaluation of the potential for expanding NPS boat tours in light of the results of the Operation Analysis of the Lowell Canal Study and in consideration of Project operation under normal and high flow conditions (including an assessment of surge gate and shut down options). The Operation Analysis of the Lowell Canal Study did not incorporate Northern Canal operations so that report is not discussed here.

As noted above, the surge gate can only be disabled when Merrimack River flows are less than 3,500 cfs, because testing of the surge gate indicated that a transient wave of less than 3,500 cfs is not enough to overtop the Great River Wall. At flows above 3,500 cfs, the surge gate is programmed to open automatically during a unit trip to prevent overtopping of the Great River Wall. The safety threshold of 3,500 cfs was agreed upon

between NPS and Boott, and FERC indicated their concurrence in the letter dated June 1, 1999. Boott acknowledges that NPS has expressed interest in raising this threshold, previously requesting a threshold of 4,000 cfs (NPS 2003), but deactivating the surge gate when flows are above 3,500 cfs defeats the purpose of its installation and presents the unacceptable risk to human life and Project safety. There are also circumstances under which Boott cannot deactivate the surge gate in order to protect worker safety and/or to ensure compliance with the Project's minimum flow requirement. For example, during any work on the crest of the Pawtucket Dam, the surge gate must remain active to prevent spillage from occurring in the event of a unit trip. Likewise, while the impoundment is being refilled following work on the spillway crest the gate must remain active to ensure minimum flow compliance should the E.L. Field Station trip off-line. In such situations Boott historically notified NPS and advised against any boat access to the Northern Canal until normal operations resume (Enel 2008).

For reasons mentioned, at this time Boott does not support broadly changing the safety threshold of 3,500 cfs in the Merrimack River to allow boat tours on the Northern Canal without a more thorough review of the 1998/1999 surge gate test data. At this time Boott has not been able to locate the 1998/1999 surge gate testing report in its records, and does not feel that it would be prudent to commit to modifying the established safety procedures until the report can be thoroughly reviewed.[11] Any modification to the established protocol will need to be carefully re-evaluated on a case-by-case basis in consultation and coordination among Boott, NPS and FERC's Division of Dam Safety and Inspections. Boott does not consider it practical or safe however to match the historical level of daily tours or six tours per day on the Northern Canal, prior to the bayboard washout incident and installation of the surge gate system. The inherent dangers of allowing tour boats to navigate a power canal during higher flows were not well understood when NPS was operating six tours a day on the Northern Canal from the late 1980s to 1994.

There may be a limited opportunity to expand the Northern Canal navigation flow threshold during the fish passage season. As proposed in the FLA, during the upstream fish passage season (which generally runs from late April through mid-July), Boott proposes to release a minimum flow of up to 500 cfs into the bypassed reach via the existing fish ladder at the Pawtucket Dam. At the time that the canal navigation protocol was developed, the fish ladder was only operated during higher flow conditions when there was spillage at the dam, thus this flow was not considered. Thus, under the proposed operating regime, flows in the Merrimack River will not be equal to Northern Canal flows, and Northern Canal flows may be equal to or below the 3,500 cfs safety threshold. Boott and NPS would need a defined protocol to evaluate this on a case-by-case basis, and in light of the results of the 1998/1999 surge test once that report is located.

[11] The report does not appear to be available via eLibrary, however there are two letters from Boott to FERC which indicate that the tests were planned to take place during the summer or fall of 1998.

FERC requested Boott consider shutdown options in their evaluation of expansion of NPS boat tours on the Northern Canal. As noted above, NPS boat tours historically only navigated the high flow portion of the Northern Canal (from Pawtucket Gatehouse to Hydro Locks) for approximately fifteen minutes but up to a half hour per tour, at around six tours a day. It is not practical for Boott to shut down or curtail operations regularly for NPS to run their boat tours for a limited amount of time on the Northern Canal. Boott currently sells all the electricity generated at the Project into the regional grid under a Power Purchase Agreement, but will likely sell energy under Independent Systems Operator – New England market conditions starting in 2023. Boott has a duty to provide clean renewable electric energy when possible to meet the demands of the electricity grid and cannot shut down or curtail operations on a regular basis.

As noted, Boott does not consider it practical or feasible to match historical levels of boat tours on the Northern Canal. The risks associated with allowing tour boats in a power canal have been evaluated since and are better understood. Additionally, NPS is not precluded from operating boat tours on the Pawtucket Canal during higher flow days when it is not appropriate to be on the Northern Canal. However, Boott believes there may be an opportunity to work with NPS to allow tour boats on occasion on the Northern Canal when Merrimack River flows are higher than 3,500 cfs but below 4,000 cfs.

Boott would be required to deviate from ROR operations in order to provide lower flow rates in the Northern Canal, as inflow to the Project would not match outflow. However, in the FLA, Boott proposed to operate the Project in a ROR mode using automatic pond level control of the E.L. Field powerhouse units, but with the stipulation that ROR operations may be temporarily modified for short periods to allow flow management for other Project and non-Project needs, e.g., for recreational purposes.

5.5.1.2 Evaluation of Effects of Project Operations on NPS Boat Tours on the Pawtucket Canal

In their March 1, 2022 Determination on Requests, FERC recommended an evaluation of the effects of Project operation on NPS boat tours, in relation to Boott's proposal to remove the majority of the canal system from the Project boundary. As discussed above in Section 5.5.1, NPS currently operates their boat tours on the Pawtucket Canal.

In their FLA filed on April 30, 2021, Boott proposed to continue to manage the canal structures, water levels and flows using best practices, consistent with current agreements with the NPS and other stakeholders. Given Boott's canal elevation agreement with NPS, Boott regularly coordinates on water elevations with the NPS and other stakeholders. Additionally, as reported in their November 1, 2021 Response to Additional Information Request, Boott is proposing to maintain specific water levels throughout the canal system as determined in consultation with NPS. The target water levels for the canals are :

- Upper canal system (including Upper Pawtucket Canal between Guard Locks and Swamp Locks): staff gage reading = 86.7 ft NGVD29;

- Lower canal system (including Lower Pawtucket Canal): staff gage reading = 71.8 ft NGVD29.

Boott's proposal to remove the downtown canal system from the Project boundary is not expected to have any effect on NPS boat tours in the Pawtucket Canal. By way of the 1995 Grant of Easement with MADCR, NPS holds recreational rights to structures of the canals to operate their boat tours. This agreement exists independently of the Project license. Boott does not hold recreational rights to the downtown canal system, and does not own structures of the Pawtucket Canal where NPS' boat tours currently operate. Additionally, Boott is proposing to continue to manage the canal structures, water levels and flows using best practices, consistent with current agreements with the NPS and other stakeholders.

5.5.1.3 Evaluation of Effects of Crest Gate on NPS Boat Tours

This section of the Recreation and Aesthetics Study report is retained from the February 25, 2021 version of this report filed with the Commission. On April 26, 2021, NPS reported that recent work by the City of Lowell to renovate the Pawtucket Street Bridge has eliminated overhead clearance issues for NPS tour boats. Therefore, this concern is resolved, but for SPD completion purposes, Boott retains this evaluation.

In their original request for this evaluation, NPS stated that their tour boats barely pass under the Pawtucket Street Bridge over Pawtucket Canal.[12] With even a 1-foot elevation rise of the Project impoundment, NPS states their boats would be unable to pass under the Pawtucket Street Bridge.

On April 18, 2013, FERC authorized Boott to replace the existing wooden flashboard system on the Project's Pawtucket Dam with a pneumatic crest gate system. FERC approved the amended Crest Gate System Operations Plan on March 30, 2015. The plan describes the operation of the pneumatic crest gate system under normal and high-water operations. Under the amended Crest Gate System Operations Plan, when there is no flow over the spillway and flows in the river are below 8,600 cfs [the combined hydraulic capacity of the E.L. Field Powerhouse (6,600 cfs) and downtown canal system (2,000 cfs)], the elevation of the reservoir would be at the normal pond elevation of 92.2 ft NGVD 29. When Merrimack River flows exceed 8,600 cfs, the Crest Gate System Operations Plan allows for a gradual rise in elevation to ± 93.2 ft NGVD 29 until flows reach approximately 11,850 cfs.[13] Under high flows exceeding 11,850 cfs and reaching 31,600 cfs, the crest gate maintains an elevation of ± 93.2 ft.

[12] NPS also stated in their letter they are barely able to pass under Central Street Bridge over the Lower Pawtucket Canal. The crest gate does not affect the elevation of waters of the Lower Pawtucket Canal and thus is not included in this analysis.

[13] 11,850 cfs was determined by adding the hydraulic capacity of the E.L. Field Powerhouse (6,600 cfs), the downtown canal system (2,000 cfs) and the extra spillway flow (3,250 cfs) allowed by the Crest Gate System Operations Plan.

On November 20, 2019, NPS filed a consultation letter with FERC and Boott. In the letter, NPS stated that Merrimack River flows must be below 12,500 cfs in order for them to operate boat tours in the Pawtucket Canal, and the operating season for boat tours runs from May 15 to October 15.

Flows from United States Geological Survey (USGS) Gage No. 01099500 *Concord R Below R Meadow Brook*, at Lowell, MA were subtracted from flows at USGS Gage No. 01100000 *Merrimack River BL Concord River at Lowell, MA* to calculate the hydrologic data tabulated in Table 5-2, presenting data at the Project from the past 30 years (water years 1987- 2016).

Table 5-2. Lowell Hydroelectric Project Hydrologic Data (1987-2016)

Month	Minimum (cfs)	90% Exceedance (cfs)	Average (cfs)	10% Exceedance (cfs)	Maximum (cfs)
January	916	3,462	7,651	12,834	39,710
February	1,478	3,272	6,813	11,415	39,180
March	1,914	4,508	11,484	21,355	50,220
April	2,765	6,558	17,901	31,178	78,890
May	2,034	4,112	10,749	18,657	88,410
June	874	2,279	6,768	13,286	44,660
July	670	1,325	4,207	9,270	29,820
August	569	1,121	3,526	6,852	30,030
September	460	1,008	3,162	6,025	32,264
October	787	1,676	5,938	12,706	50,150
November	1,345	2,888	7,978	14,747	30,990
December	1,839	3,472	9,141	17,243	34,810
Annual	460	1,723	7,941	17,059	88,410

The Project maintains a normal pond elevation of 92.2 ft NGVD 29 when flows in the Merrimack River are up to 8,600 cfs. According to USGS gage data presented in Table 5-2, average flows during the operating season (May 15 through October 15) for NPS boat tours generally do not exceed 8,600 cfs. May is the only month with an average Merrimack River flow above 8,600 cfs.

As described above, when Merrimack River flows exceed 8,600 cfs, the crest elevation gradually rises to 93.2 ft NGVD 29 until flows reach 11,850 cfs. Ultimately, only between Merrimack River flows of 11,850 cfs and 12,500 cfs (NPS' self-reported limit), are NPS boats supposedly unable to pass under Pawtucket Street Bridge. This is a relatively narrow window, especially since the average flow for the entire operating season never reaches 11,850 cfs, and a 10% chance of exceedance of 11,850 cfs only occurs in May, June, and October. The majority of flows through the Lowell Project are a direct result of the annual hydrologic cycle, much of which is unpredictable and inconsistent. Merrimack

River flows high enough to raise the pond elevation 1-foot are seemingly just as likely to rise above NPS' self-reported threshold.

5.5.2 Northern Canal Walkway

The Northern Canal Walkway opens seasonally (May 15 through October 15) when flow rates in the Merrimack River and Northern Canal are lower than 3,500 cfs. This threshold was determined because a study demonstrated that a surge wave above 3,500 cfs in the Northern Canal poses a risk of overtopping the Great River Wall. In 1999, the Licensee completed construction of the surge gate, designed to attenuate the surge wave in the canal that occurs during sudden plant shutdown. A test of the surge gate revealed that the gate did attenuate the resulting transient wave. However, as reported to FERC, the test indicated when fully opened, the significant volume of discharge through the surge gate is hazardous to any persons in the riverbed below or near the gate. FERC directed Boott to design a Public Safety Plan to warn the public of this hazard, which included warning signs, sirens and beacons installed at various locations along and in the Merrimack River (FERC 2000). Accordingly, to be conservative and assure public safety, the 3,500 cfs threshold to open the Northern Canal Walkway remained despite the installation of the surge gate.

Boott acknowledges that the 3,500 cfs threshold is strict. However, the surge gate must open during a unit trip when Merrimack River flows are over 3,500 cfs, otherwise there is a threat of overtopping the Great River Wall and the Northern Canal Walkway. Conversely, the significant amount of flow that is released through the surge gate when opened poses an extreme risk to anyone below on the rocky shore or in the riverbed. NPS, City of Lowell, or MADCR staffing/guarding of the area may mitigate this risk below the surge gate, but due to the lack of any emergency access to that area it is not recommended by Boott.

Boott analyzed USGS data to determine how many days during the recreation season (May 15 through October 15) the Northern Canal Walkway is closed due to Project operations. Project hydrology can be determined by subtracting flows from USGS Gage No. 01099500 (*Concord R Below R Meadow Brook, at Lowell, MA*) from USGS Gage No. 01100000 (*Merrimack River BL Concord River at Lowell, MA*). Using the daily mean average means for both gages for the period of record of January 1, 2000 through January 1, 2022, Boott has determined on average, the NPS closes the Northern Canal Walkway 125 days during the recreation season. According to the LNHP website (NPS 2022), they make this determination each morning during the season by reviewing the most recent instantaneous value recorded at USGS Gage No. 01100000.

5.6 Visual Survey for Vegetation Growth

In total, 96 Vegetation Polygons (representing 80% of the total survey data collected in the study area) and 24 VPs (representing 20% of the total survey data collected in the study area) were mapped between September 25 and September 27, 2019 (Appendix G;

Appendix H). As shown in Table 5-3, the total study area encompassed approximately 44 acres and mapped vegetation on/along canal walls accounted for approximately 5 acres (11%) of the study area[14]. The Pawtucket Canal (19.63 acres; 44% of the total study area), Northern Canal (11.67 acres; 26% of the total study area), and Western Canal (5.51 acres; 13% of the total study area) represent more than 80 percent of the total study area (Table 5-3, Appendix G).

Maps showing the results of the vegetation assessment and mapping within the study area are illustrated in a 21-sheet, 11 by 17-inch vegetation type map set with numbered polygons (e.g., 1, 2) and VPs (e.g., VP1, VP2) for each vegetation polygon and/or VP, respectively in Appendix G. Results from the canal wall vegetation mapping are compiled in Appendix H and field reconnaissance data is summarized in Appendix I to this study report.

Table 5-3. Percent total acreage and mapped vegetation acreage of the six major canals associated with the Lowell Project canal system

Canal	Area (acres)	Percentage (%) of Total Study Area	Mapped Vegetation Area (acres)	Percentage (%) of Total Study Area with Mapped Vegetation
Eastern Canal	4.03	9%	0.93	2%
Hamilton Canal	2.01	5%	0.35	1%
Merrimack Canal	1.40	3%	0.38	1%
Northern Canal	11.67	26%	0.89	2%
Pawtucket Canal	19.63	44%	1.33	3%
Western Canal	5.51	13%	0.90	2%
Total	**44.25**	**100%**	**4.78**	**11%**

Pursuant to the approved study plan, vegetation type assessments were completed in the Pawtucket Canal, Northern Canal, Western Canal, Merrimack Canal, Eastern Canal, and Hamilton Canal. In addition, the shoreline/canal type was characterized by dominant features found in each of the mapped polygons and VPs. Field inventory documentation, including a map identifying each polygon or VP, representative photographs, and a description of the vegetation type observed at each polygon or VP is presented in Appendices G-J to this study report.

5.6.1 Eastern Canal

The vegetation mapping and characterization effort was conducted in the Eastern Canal on September 25, 2019. Sheets 8, 11, 12, and 16 present mapped vegetation types

[14] VPs are not included in mapped vegetation acreage calculations because they represent a single point(s) on a canal wall.

within the Eastern Canal (Appendix G). Additional canal-specific information describing vegetation and shoreline/canal features is provided in Appendix H.

The Eastern Canal study area represents 4.03 acres (approximately 9%) of the total study area (Table 5-3, Appendix G). Three (3) VPs were mapped in the Eastern Canal, representing approximately 13 percent of total mapped VPs in the total study area. At the time of the study, mapped VPs in the Eastern Canal had a dominant vegetation type of Scrub-Shrub (100% of the total). The dominant shoreline type of mapped VPs within the Eastern Canal is either Block Wall (approximately 33.3% of the total) or Block Wall/Concrete/Stone Wall Mix (approximately 66.7% of the total) (Appendix G, Appendix H, and Appendix I).

Fifteen (15) Vegetation Polygons were mapped in the Eastern Canal, representing approximately 16 percent of total mapped Vegetation Polygons in the total study area (Appendix G, Appendix H, and Appendix I). Vegetation was mapped on 0.93 acres of the Eastern Canal walls, representing approximately 19 percent of the total mapped vegetation area within the total study area and approximately 23 percent of the Eastern Canal study area. At the time of the study, the majority of mapped Vegetation Polygons in the Eastern Canal had a dominant vegetation type of Mixed (approximately 62% of the total). The dominant shoreline type of mapped Vegetation Polygons within the Eastern Canal is either Block Wall (approximately 80% of the total) or Block Wall/Concrete/Stone Wall Mix (approximately 20%) (Appendix G, Appendix H, and Appendix I).

Mapped Vegetation Polygons within the Eastern Canal with a dominant shoreline type of Block Wall had a dominant vegetation type of Mixed (0.43 acres; approximately 58% of the total) at the time of the study. Scrub-Shrub (0.17 acres; approximately 23% of the total) and Herbaceous (0.12 acres; approximately 16% of the total) were present in lesser amounts, with Trees (0.02 acres; approximately 3% of the total) being minimal at the time of the study. Mapped Vegetation Polygons within the Eastern Canal with a dominant shoreline type of Block Wall/Concrete/Stone Wall Mix had a dominant vegetation type of Mixed (0.15 acres; approximately 79% of the total) or Trees (0.04 acres; approximately 21% of the total) at the time of the study (Appendix G, Appendix H, and Appendix I).

At the time of the study, no mapped VPs or Vegetation Polygons within the Eastern Canal had a dominant vegetation type of Forested. No mapped VPs or Vegetation Polygons within the Eastern Canal have dominant shoreline types of Concrete, Earthen/Terrestrial Cultural, or Stone Wall (Appendix G, Appendix H, and Appendix I).

5.6.2 Hamilton Canal

The vegetation mapping and characterization effort was conducted in the Hamilton Canal on September 25, 2019. Sheets 19 and 20 present mapped vegetation types within the Hamilton Canal (Appendix G). Additional canal specific information describing vegetation and shoreline/canal features is provided in Appendices H and I.

The Hamilton Canal study area represents 2.01 acres (approximately 5%) of the total study area (Table 5-3). One (1) VP was mapped in the Hamilton Canal, representing approximately 4 percent of total mapped VPs in the total study area. At the time of the study, the mapped VP in the Hamilton Canal had a dominant vegetation type of Herbaceous (100% of the total). The dominant shoreline type of the mapped VP within the Hamilton Canal is Block Wall/Concrete/Stone Wall Mix (100% of the total) (Appendix G, Appendix H, and Appendix I).

Seven (7) Vegetation Polygons were mapped in the Hamilton Canal, representing approximately 7 percent of total mapped Vegetation Polygons in the total study area. Vegetation was mapped on 0.35 acres of the Hamilton Canal walls, representing approximately 7 percent of the total mapped vegetation area within the total study area and approximately 17 percent of the Hamilton Canal study area. At the time of the study, the majority of mapped Vegetation Polygons in the Hamilton Canal had a dominant vegetation type of Mixed (approximately 74% of the total). The majority of mapped Vegetation Polygons in the Hamilton Canal have a dominant shoreline type of Block Wall/Concrete/Stone Wall Mix (approximately 83% of the total) (Appendix G, Appendix H, and Appendix I).

Mapped Vegetation Polygons within the Hamilton Canal with a dominant shoreline type of Block Wall/Concrete/Stone Wall Mix had a dominant vegetation type of Mixed (0.26 acres; approximately 90% of the total), Herbaceous (0.02 acres; approximately 7% of the total), or Trees (0.01 acres; approximately 3% of the total) at the time of the study. Mapped Vegetation Polygons within the Hamilton Canal that had a dominant shoreline type of Block Wall had a dominant vegetation type of Trees (0.03 acres; 50% of the total) or Scrub-Shrub (0.03 acres; 50% of the total) at the time of the study. (Appendix G, Appendix H, and Appendix I)

At the time of the study, no mapped VPs or Vegetation Polygons within the Hamilton Canal had a dominant vegetation type of Forested. No mapped VPs or Vegetation Polygons within the Hamilton Canal have a dominant shoreline type of Concrete, Earthen/Terrestrial Cultural, or Stone Wall (Appendix G, Appendix H, and Appendix I).

5.6.3 Merrimack Canal

The vegetation mapping and characterization effort was conducted in the Merrimack Canal on September 25, 2019. Sheets 11 and 15 present mapped vegetation types within the Merrimack Canal (Appendix G).

The Merrimack Canal study area represents 1.4 acres (approximately 3%) of the total study area (Table 5-3). No VPs were mapped in the Merrimack Canal at the time of the study (Appendix G, Appendix H, and Appendix I).

Nine (9) Vegetation Polygons were mapped in the Merrimack Canal, representing approximately 9 percent of total mapped Vegetation Polygons in the total study area. Vegetation was mapped on 0.38 acres of the Merrimack Canal walls, representing

approximately 8 percent of the total mapped vegetation area within the total study area and approximately 27 percent of the Hamilton Canal study area. At the time of the study, the majority of mapped Vegetation Polygons in the Merrimack Canal had a dominant vegetation type of Herbaceous (approximately 53% of the total). The majority of mapped Vegetation Polygons in the Merrimack Canal have a dominant shoreline type of Block Wall/Concrete/Stone Wall Mix (approximately 54% of the total), followed closely by Block Wall (approximately 46% of the total) (Appendix G, Appendix H, and Appendix I).

Mapped Vegetation Polygons within the Merrimack Canal with a dominant shoreline type of Block Wall/Concrete/Stone Wall Mix had a dominant vegetation type of Herbaceous (0.15 acres; approximately 75% of the total) or Scrub-Shrub (0.05 acres, approximately 25% of the total) at the time of the study. Mapped Vegetation Polygons within the Merrimack Canal with a dominant shoreline type of Block Wall had a dominant vegetation type of Mixed (0.12 acres; 71% of the total) or Herbaceous (0.05 acres; 29% of the total), at the time of the study. Trees represented less than 1 percent (0.003 acres) of the total mapped vegetation area within the Merrimack Canal study area and were the dominant vegetation type of mapped Vegetation Polygons that have a dominant shoreline type of Concrete. (Appendix G, Appendix H, and Appendix I)

At the time of the study, no mapped Vegetation Polygons within the Merrimack Canal had a dominant vegetation type of Forested. No mapped Vegetation Polygons within the Merrimack Canal have a dominant shoreline type of Earthen/Terrestrial Cultural or Stone Wall (Appendix G, Appendix H, and Appendix I).

5.6.4 Northern Canal

The vegetation mapping and characterization effort was conducted in the Northern Canal on September 26 and 27, 2019. Sheets 2, 3, 5, and 6 present mapped vegetation types within the Northern Canal (Appendix G).

As previously described, the Northern Canal study area represents 11.67 acres (approximately 26%) of the total study (Table 5-3). Eight (8) VPs were mapped in the Northern Canal, representing approximately 33 percent of total mapped VPs in the total study area. At the time of the study, the dominant vegetation type of mapped VPs in the Northern Canal was either Trees (50% of the total) or Scrub-Shrub (50% of the total). The dominant shoreline type of all mapped VPs within the Northern Canal is Block Wall (100% of the total) (Appendix G, Appendix H, and Appendix I)

Thirteen (13) Vegetation Polygons were mapped in the Northern Canal, representing approximately 14 percent of total mapped Vegetation Polygons in the total study area. Vegetation was mapped on 0.89 acres of the Northern Canal walls, representing approximately 19 percent of the total mapped vegetation area within the total study area and approximately 8 percent of the Northern Canal study area. At the time of the study, the majority of mapped Vegetation Polygons in the Northern Canal had a dominant vegetation type of Mixed (approximately 32% of the total), followed closely by Forested

and Herbaceous (each representing 28% of the total). The majority of mapped Vegetation Polygons in the Northern Canal have a dominant shoreline type of Block Wall (approximately 53% of the total) (Appendix G, Appendix H, and Appendix I).

Mapped Vegetation Polygons within the Northern Canal with a dominant shoreline type of Block Wall had a dominant vegetation type of Forested (0.19 acres; approximately 40% of the total), Mixed (0.16 acres; approximately 34% of the total); Scrub-Shrub (0.08 acres; approximately 17% of the total), Trees (0.03 acres; approximately 6% of the total); or Herbaceous (0.01 acres; approximately 2% of the total) at the time of the study. Mapped Vegetation Polygons within the Northern Canal with a dominant shoreline type of Bock Wall/Concrete/Stone Wall Mix had a dominant vegetation type of Forested (0.05 acres; 17% of the total) or Herbaceous (0.24 acres; 83% of the total) at the time of the study. Mapped Vegetation Polygons within the Northern Canal with a dominant shoreline type of Earthen/Terrestrial Cultural had a dominant vegetation type of Mixed (0.13 acres; 100% of the total) at the time of the study. (Appendix G, Appendix H, and Appendix I)

At the time of the study, the Northern Canal is the only canal with Forested vegetation observed on the dominant shoreline type of Block Wall. No mapped VPs or Vegetation Polygons within the Northern Canal had a dominant shoreline type of Concrete or Stone Wall (Appendix G).

5.6.5 Pawtucket Canal

The vegetation mapping and characterization effort was conducted on the Pawtucket Canal on September 25 and 26, 2019. An NPS boat was used to collect data in the Pawtucket Canal from the Swamp Locks and Dam to the Merrimack River on September 26, 2019. Additional data was collected for the remainder of the Pawtucket Canal on foot from the shoreline on September 25 and 26, 2019. Sheets 13 and 15 through 21 present mapped vegetation types within the Pawtucket Canal (Appendix G). Additional canal specific information describing vegetation and shoreline/canal features is provided in Appendix H and Appendix I.

As previously described, the Pawtucket Canal study area represents 19.63 acres (approximately 44%) of the total study area (Table 5-3, Appendix G). Eight (8) VPs were mapped in the Pawtucket Canal, representing approximately 33 percent of total mapped VPs in the total study area (Appendix G). At the time of the study, the majority of mapped VPs within the Pawtucket Canal had a dominant vegetation type of Trees (approximately 63% of the total). The majority of mapped VPs within the Pawtucket Canal have a dominant shoreline type of Block Wall (38% of the total), followed closely by Block Wall/Concrete/Stone Wall Mix and Stone Wall (each representing 25% of the total) (Appendix G, Appendix H, and Appendix I).

Thirty-two (32) Vegetation Polygons were mapped in the Pawtucket Canal, representing approximately 33 percent of total mapped Vegetation Polygons in the total study area. Vegetation was mapped on 1.33 acres of the Pawtucket Canal walls, representing approximately 28 percent of the total mapped vegetation area within the total study area

and approximately 7 percent of the Pawtucket Canal study area. At the time of the study, the majority of mapped Vegetation Polygons in the Pawtucket Canal had a dominant vegetation type of Trees (53% of the total). The majority of mapped Vegetation Polygons in the Pawtucket Canal have a dominant shoreline type of Block Wall (approximately 85% of the total) (Appendix G, Appendix H, and Appendix I).

Mapped Vegetation Polygons within the Pawtucket Canal with a dominant shoreline type of Block Wall had a dominant vegetation type of Trees (0.61 acres; approximately 54% of the total), Mixed (0.42 acres; 37% of the total), Scrub-Shrub (0.08 acres; 8% of the total), or Herbaceous (0.01 acres; 1% of the total) at the time of the study. The majority of mapped Vegetation Polygons within the Pawtucket Canal with a dominant shoreline type of Block Wall/Concrete/Stone Wall Mix had a dominant vegetation type of Scrub-Shrub (0.03 acres; 34% of the total) at the time of the study. Mapped Vegetation Polygons within the Pawtucket Canal with a dominant shoreline type of Concrete had a dominant vegetation type of either Mixed (0.04 acres; 50% of the total) or Trees (0.04 acres; 50% of the total) at the time of the study and mapped Vegetation Polygons within the Pawtucket Canal with a dominant shoreline type of Stone Wall had a dominant vegetation type of Trees (0.03 acres; 100% of the total) at the time of the study. (Appendix G, Appendix H, and Appendix I).

At the time of the study, no mapped VPs or Vegetation Polygons within the Pawtucket Canal had a dominant vegetation type of Forested. No mapped VPs or Vegetation Polygons within the Pawtucket Canal have a dominant shoreline type of Earthen/Terrestrial Cultural. The Pawtucket Canal is the only canal in the total study area that had vegetation mapped on the dominant shoreline type of Stone Wall (Appendix G, Appendix H, and Appendix I).

It should be noted, based on the elevation of the water within the Pawtucket Canal at the time of the investigation, that the majority of the upstream extent of the Pawtucket Canal, upstream of the NPS Guard Lock and Gates Facility, is dominated by typical forested/riparian vegetation on earthen stream embankments and the canal in this area is assumed to not be bordered by one of the shoreline/canal types described in Table 4-2, therefore, no mapping of dominant vegetation types occurred in this area.

5.6.6 Western Canal

The vegetation mapping and characterization effort was conducted in the Western Canal on September 25 and 26, 2019. Mapbook sheets 6, 7, 10, 14, and 19 present mapped vegetation types within the Western Canal (Appendix G). Additional canal specific information describing vegetation and shoreline/canal features is provided in Appendix H and Appendix I.

As previously described, the Western Canal study area represents 5.51 acres (13%) of the total study area (Table 5-3, Appendix G). Four (4) VPs were mapped in the Western Canal, representing approximately 17 percent of total mapped VPs in the total study

area. At the time of the study, the majority of mapped VPs in the Western Canal had a dominant vegetation type of Scrub-Shrub (approximately 50% of the total). Mapped VPs in the Western Canal have a dominant shoreline type of either Block Wall (75% of the total) or Block Wall/Concrete/Stone Wall Mix (Appendix G, Appendix H, and Appendix I).

Twenty (20) Vegetation Polygons were mapped in the Western Canal, representing approximately 21 percent of total mapped Vegetation Polygons in the total study area. Vegetation was mapped on 0.9 acres of the Western Canal walls, representing approximately 19 percent of the total mapped vegetation area within the total study area and approximately 16 percent of the Western Canal study area. At the time of the study, the majority of mapped Vegetation Polygons in the Western Canal had a dominant vegetation type of Forested (approximately 53% of the total). The majority of mapped Vegetation Polygons in the Western Canal have a dominant shoreline type of Block Wall/Concrete/Stone Wall Mix (approximately 77% of the total) (Appendix G, Appendix H, and Appendix I).

Mapped Vegetation Polygons within the Western Canal with a dominant shoreline type of Block Wall/Concrete/Stone Wall Mix had a dominant vegetation type of Forested (0.48 acres; 62% of the total), Mixed (0.16 acres; approximately 21% of the total), or Herbaceous (0.05 acres; 6% of the total) at the time of the study. Mapped Vegetation Polygons within the Western Canal with a dominant shoreline type of Block Wall had a dominant vegetation type of Mixed (0.01 acres; 8% of the total); Herbaceous (0.09 acres; 75% of the total); or Scrub-Shrub (0.02 acres; 17% of the total) at the time of the study. No mapped Vegetation Polygons within the Western Canal had dominant shoreline type of Concrete, Earthen/Terrestrial Cultural, or Stone Wall (Appendix G, Appendix H, and Appendix I).

5.7 Visual Survey for Waterborne Trash

Pursuant to the RSP, on April 9, 2020, Boott mapped areas within the canal system owned or under the control of Boott where waterborne trash may be a potential concern. The amount and type of waterborne trash that accumulates within the Project Boundary can vary according to several factors including the season, Project operations, the magnitude and duration of the flow events. During the visual survey for waterborne trash, the USGS Gage 01100000 Merrimack River BL Concord River at Lowell, MA, reported a discharge of over approximately 16,000 cfs (USGS 2020), and Boott's operations data reported an inflow of 14,500 cfs.[15]

Accumulated waterborne trash includes material floating on the impoundment surface and/or found on the surface of the canal system. Most of the waterborne trash accumulation within the Lowell Canal system appears to be derived from upstream

[15] Inflow to the project is typically estimated as flow reported at USGS Gage 01100000 Merrimack River BL Concord River at Lowell, MA minus the flow reported at USGS 01099500 Concord R Below R Meadow Brook, at Lowell, MA.

inputs (the Merrimack River) as well as direct canal inputs (accidental and intentional littering) and from runoff events (also likely from accidental and intentional littering).

In total, eight (8) areas of waterborne trash totaling 0.21 acres (representing 0.48% of the total study area) were mapped on April 9, 2020 (Appendix K) as well as three additional areas of accumulated trash on the canal bed and a single area with a waterborne sheen. The total study area encompassed approximately 44 acres and as shown in Table 5-4 all mapped areas within the canal were 3.531 acres or approximately 154,000 square feet.

Maps showing the results of the waterborne trash assessment and mapping within the study area are illustrated by a map set with numbered polygons (e.g., WBT-1, WBT-2) for each mapped waterborne trash polygon (Appendix K). Results from the waterborne trash mapping are compiled in Appendix K and field reconnaissance data is summarized in Table 5-4 and Photo 5-2 through Photo 5-11.

Table 5-4. Percent total acreage of waterborne trash mapped within the Lowell canal system.

Mapped Polygon Identifier	Location	Mapped Area (acres)	Mapped Area (sq. ft.)	Canal Water Level	Potential Local Cause
WBT-1	Merrimack River at Fishway Exit	0.007	286.0	High	Eddy Area at head of fishway
WBT-2	Merrimack River Upstream of Pawtucket Gatehouse	0.063	2,765.0	High	Gatehouse
WBT-3	Western Canal at Merrimack Street	0.011	488.0	Normal	Iron support beams for bridge
WBT-4	Western Canal at Moody Street	0.038	1,674.0	Normal	Gate
WBT-5	Northern Canal and Western Canal Junction	0.013	545.0	Normal	Fremont Gatehouse, structure creating eddy
WBT-6	Merrimack Canal at Market Street	0.024	1,045.0	Normal	Gates
WBT-7	Pawtucket Canal at Guard Locks	0.049	2,120.0	Normal	Gatehouse
WBT-8	Hamilton Canal adjacent to Hamilton Mills	0.004	182.0	Normal	End of Canal (Intake)
CBT-1	Pawtucket Canal from Industrial Canyon to Kerouac Park	1.833	79,832.0	Low	Canal dewatered
CBT-2	Pawtucket Canal adjacent to Appleton Mills	0.537	23,411.0	Low	Canal dewatered

Mapped Polygon Identifier	Location	Mapped Area (acres)	Mapped Area (sq. ft.)	Canal Water Level	Potential Local Cause
CBT-3	Eastern Canal adjacent to Tsongas and Boarding House Park	0.468	20,395.0	Low	Canal dewatered
WBS-1	Merrimack Canal adjacent to Visitor Center	0.484	21,066.0	Normal	Unknown sheen
	Total	**3.531**	**153,809.0**	**-**	**-**

Pursuant to the approved study plan, waterborne trash assessments were completed in the Pawtucket Canal, Northern Canal, Western Canal, Merrimack Canal, Eastern Canal, Hamilton Canal, and in the Merrimack River upstream of the dam and Northern Canal intake. Field inventory documentation, including a map identifying each polygon and a description of the type of waterborne trash observed at each polygon is presented in Appendix K to this study report.

Boott surveyed the Lowell canal system on foot and by vehicle to visually inspect and document waterborne trash within the study area. Observations were recorded regarding evidence and location of waterborne trash. Data collected during this portion of the survey included field notes, digitized locations of waterborne trash, and photographic documentation.

In addition to mapping waterborne trash, during incidental observations for other field efforts, Boott observed aged substrate trash accumulation in the bottom of the Eastern Canal and portions of the Pawtucket Canal during dewatered for various construction and maintenance activities not associated with hydroelectric operations. This aged substrate trash is further described in Section 5.6.9 below and is also depicted on the map of the study area in Appendix K.

Boott also observed a surface sheen on the Merrimack Canal on April 9, 2020. This sheen is further described in Section 5.6.10 below and is also depicted on the map of the study area in Appendix K.

5.7.1 Merrimack River at the Fishway Exit

Waterborne trash observed on the Merrimack River fishway exit (WBT-1) encompassed a water surface area of approximately 0.007 acres (Table 5-4). This trash appears to accumulate in an eddy type feature and above the intake water for the fishway. Waterborne trash consisted of buoys, plastics, shoes, rubber mats, foam, and bait containers (No photo available).

5.7.2 Merrimack River Upstream of the Pawtucket Gatehouse

Waterborne trash observed on the Merrimack River upstream of the Pawtucket Gatehouse (WBT-2) encompassed a water surface area of approximately 0.063 acres (Table 5-4). This trash appears to accumulate in an eddy type feature and above the gatehouse intakes. Waterborne trash consisted of logs, boards, organic debris, plastic cups, plates, shoes, water bottles, buoys, plastics, foam, and bait containers (Photo 5-1).

Photo 5-1. Waterborne trash on the Merrimack River upstream of the Northern Canal Gate entrance.

5.7.3 Western Canal at Merrimack Street

Waterborne trash observed on the Western Canal at Merrimack Street (WBT-3) encompassed a water surface area of approximately 0.011 acres (Table 5-4). This trash appears to be behind steel beams across the canal, potentially for structural support of the road bridge for Merrimack Street. Waterborne trash consisted of foam plates, plastic cups, rubber balls plastic jugs, plastic wrappers and bags (Photo 5-2).

Photo 5-2. Waterborne trash on the Western Canal at Merrimack Street.

5.7.4 Western Canal at Moody Street

Waterborne trash observed on the Western Canal at Moody Street (WBT-4) encompassed a water surface area of approximately 0.038 acres (Table 5-4). This trash appears to accumulate behind an operable gate structure. Waterborne trash consisted of tires, umbrellas, foam plates, plastic cups, plastic bottles, rubber balls, plastic jugs, plastic wrappers, foam boards and bags (Photo 5-3).

Photo 5-3. Waterborne trash on the Western Canal at Moody Street.

5.7.5 Northern Canal and Western Canal Junction at the Tremont Gatehouse and Powerhouse

Waterborne trash observed on the Northern Canal and Western Canal junction at the Tremont Gatehouse and Powerhouse (WBT-5) encompassed a water surface area of approximately 0.013 acres (Table 5-4). This trash appears to accumulate in an eddy within a large indent within the canal wall structure located just upstream of the Fremont Gatehouse. Waterborne trash consisted of foam board pieces, plastic cups, foam plates, foam bait containers, shoes, plastic bottles, and organic debris (Photo 5-4).

Photo 5-4. Waterborne trash on the Western Canal at the Northern Canal Junction.

5.7.6 Merrimack Canal at Market Street

Waterborne trash observed on the Merrimack Canal at Market Street (WBT-6) encompassed a water surface area of approximately 0.024 acres (Table 5-4). This trash appears to accumulate behind the operational gates at this location. Waterborne trash consisted of plastic bottles, foam containers, foam cups, plastic bags, rubber balls, diapers, glass bottles, wood, plastic wrappers, soft drink cans, and organic debris (Photo 5-5).

Photo 5-5. Waterborne trash on the Merrimack Canal at Market Street.

5.7.7 Pawtucket Canal at the Guard Lock and Gate Facility

Waterborne trash observed on the Pawtucket Canal at the Guard Lock and Gate Facility (WBT-7) encompassed a water surface area of approximately 0.049 acres (Table 5-4). This trash appears to accumulate upstream of the Guard Lock water release structure on river left. Waterborne trash consisted of paper, foam boards, all types of balls (rubber, plastic, baseball, soccer, etc.), organic matter, logs, tires, construction barrels, plastic bottles, cans, foam containers (Photo 5-6).

5.7.8 Hamilton Canal Adjacent to Hamilton Mills

Waterborne trash observed at the end of Hamilton Canal at the intake (WBT-8) encompassed a water surface area of approximately 0.004 acres (Table 5-4). This trash appears to accumulate at the intake (No photo available).

Photo 5-6. Waterborne trash on the Pawtucket Canal at Guard Lock and Gate Facility.

5.7.9 Observations of Aged Substrate Trash Accumulation on the bottom of the Eastern Canal and Portions of the Bottom of the Pawtucket Canal

Observations of substrate trash accumulation on the bottom of the Eastern Canal and portions of the Pawtucket Canal occurred during a dewatering event associated with non-Project construction and maintenance activities. This substrate accumulation encompassed an area of approximately 0.468 acres (Table 5-4) in the Eastern Canal, approximately 1.833 acres in the Pawtucket Canal near “Industrial Canyon”, and 0.537 acres in the Pawtucket Canal immediately downstream of the Swamp Locks. The substrate trash in the Eastern Canal consist largely of iron, traffic cones, cans, and woody debris. In the Pawtucket Canal near Industrial Canyon, the substrate trash consists mostly of wood, iron, and plastic trash. The Pawtucket Canal downstream of Swamp Locks consists mostly of metal and some minimal floating plastic bottles (Photo 5-7 through Photo 5-10).

Photo 5-7. Substrate trash on bottom of Eastern Canal across from Boarding House Park.

Photo 5-8. Substrate trash on bottom of Eastern Canal across from Boott Cotton Mills Museum and Tsongas Industrial History Center.

Photo 5-9. Substrate debris at the bottom of Pawtucket Canal adjacent to Appleton Mills and downstream of Swamp Locks.

Photo 5-10. Waterborne trash immediately downstream of Swamp Locks.

5.7.10 Observations of Surface Sheen

Boott also observed a surface sheen on the Merrimack Canal on April 9, 2020. The location of the source of this sheen was undetermined but appear to begin at or upstream of the Swamp Locks (Photo 5-11).

Photo 5-11. Surface sheen observed on April 9, 2020 on Merrimack Canal adjacent to the Visitor Center and downstream of the Swamp Locks.

6 Summary and Discussion

6.1 Field Inventory and Visitor Use Data

The results from the field inventory and the visitor use data (personal interviews, field reconnaissance, and online surveys) are consistent with the literature review. The field inventory identified extensive recreational facilities in the Project area, with the available amenities reported in good condition. Of the fifty-three (53) personal interviews and ninety-six (96) online recreation surveys completed, the respondents are typically regular visitors who visit three or more times per year. Respondents travelled an average of 7.3 miles (personal interviews) and 11 miles (online survey respondents) to the Project area. The most reported recreational activities are light activities such as walking, dog walking, and jogging, with most respondents rating their overall experience of recreational activities at the Project as “acceptable” or “totally acceptable.” The most frequently visited recreational facilities in the Project area were the Lowell Heritage State Park, the Rourke Brothers Boat Ramp, Chelmsford Boat Access, Merrimack Trail System, and LNHP-related facilities. Respondents both in-person and online tended to rate their

overall experience at these specific recreation facilities as “acceptable” or “totally acceptable.”

6.2 Evaluation of Recreational Access

The opportunities for expansion of recreational opportunities in the Project canals are limited. MADCR exclusively owns all rights to allow recreation on or in the Project canals and holds easement rights to install recreational access points. Boott’s proposal to remove the majority of the downtown canal system from the Project boundary does not affect the recreational rights held by MADCR, and granted to NPS. Boott identified segments of the Merrimack Canal, Western Canal, and Northern Canal as surface water recreation areas potentially compatible with public safety and recreational and property rights. Boott’s proposal to remove the majority of the downtown canal system from the Project boundary is not expected to affect recreational access (including NPS boat tours) in the downtown canal system. During the recreation season, which generally corresponds with lower flows in the Merrimack River, Boott infrequently operated the downtown mill power stations. Therefore, the removal of the downtown system from the new FERC license is not going to noticeably impact recreation opportunities in the canal system.

Boott also evaluated the effects of water levels and flows and crest gate operations on NPS-boat tours and the Northern Canal Walkway access. Between flows of 11,850 cfs and 12,500 cfs (NPS’ self-reported limit), NPS boats are reportedly unable to pass under Pawtucket Street Bridge. This is a relatively narrow difference, and such high flows are not common during the operating season (May 15 to October 15).

Boott also researched the 3,500 cfs threshold to open the Northern Canal Walkway. While the surge gate was installed to mitigate the risk of overtopping of the Great River Wall, the volume of water released from the surge gate is considered dangerous to any persons below on the riverbed or bank.

6.3 Visual Survey for Vegetation Growth

A wide variety of vegetation types, occurrences, and distribution, ranging from herbaceous, non-woody plants to forested areas of trees and underbrush, and shoreline/canal types, ranging from earthen embankments to placed, uniformly sized blocks, were observed during the canal wall vegetation surveys. The following summary statements are based on an analysis of survey results (Appendix G-Appendix I):

- Mapped vegetation[16] was greatest in the Pawtucket Canal (1.33 acres; approximately 28% of the total study area), followed by the Eastern Canal (0.93 acres), Western Canal (0.90 acres), and Northern Canal (0.89 acres) (each representing approximately 19% of the total study area).

[16] VPs are not included in mapped vegetation acreage calculations because they represent a single point(s) on a canal wall.

- At the time of the study, most mapped VPs within the total study area had a dominant vegetation type of Scrub-Shrub (46% of the total VP count), followed closely by Trees (38% of the total VP count). The majority of mapped Vegetation Polygons within the total study area had a dominant vegetation type of Mixed (41% of the total mapped vegetation area) at the time of the study.
- Within the total study area, most mapped VPs had a dominant shoreline type of Block Wall (63% of the total VP count). The majority of mapped Vegetation Polygons within the total study area also had a dominant shoreline type of Block Wall (58% of the total mapped vegetation area).
- Mapped Vegetation Polygons with a dominant vegetation type of Forested were only recorded within the Western Canal (53% of the Western Canal study area), and the Northern Canal (28% of the Northern Canal study area) at the time of the study. Forested vegetation was recorded on Block Wall (0.19 acres; approximately 4% of total mapped vegetation area) and Block/Wall/Concrete Stone Wall Mix (0.53 acres; approximately 11% of the total mapped vegetation area) at the time of the study.

6.4 Visual Survey for Waterborne Trash

The surveys for waterborne trash have shown that waterborne trash accumulates within the Project's canal system, and these accumulations are somewhat dependent on the level of the water within the canals as well as the required operation of some of the NPS gates within the study area. For example, NPS gates that are operated on a routine basis had minimal signs of waterborne trash associated with them, while others that are largely in the closed position tended to have accumulations of waterborne trash behind them at varying densities.

The combination of past and present land use activities in and around the Project area have contributed and will likely continue to contribute to the accumulation of waterborne trash within the Project's canal system that occur in the study area today (e.g., industrialization, commercial development, residential areas in close proximity to canals, etc.). However, the complexity and diversity of historical and current land use activities in the study area create a problem for tracing and identifying the sources of waterborne trash and its movement and distribution within the study area. Waterborne trash consisted of common materials such as foam board pieces, plastic cups, foam plates, foam bait containers, shoes, plastic bottles, and organic debris.

It is well known that many types of land uses contribute to the accumulations of waterborne trash including stormwater drainage systems, upstream sources, inappropriately discarded trash, natural events (woody debris), densely populated areas, etc. Roads, construction, recreation, residential developments, and commercial and industrial developments all can contribute to the problem. Ongoing Project operation and maintenance has very little potential to cause and/or significantly contribute to the waterborne trash accumulation areas observed during the study.

7 Variances from FERC-Approved Study Plan

The Recreation and Aesthetics Study was conducted in full accordance with the methods described in the FERC-approved study plan except for the following variances:

- When conducting personal interviews at the recreation facilities identified in consultation with stakeholders, field technicians generally attempted to visit each of the selected recreation facilities during every survey event. In some instances, field technicians encountered conditions at recreation facilities that presented safety risks. In such instances, field technicians avoided those facilities during the survey event and documented the unsafe conditions encountered that prevented personal interviews from occurring.
- When conducting canal wall vegetation surveys within/along the six canals identified, field technicians generally attempted to survey the entirety of the canal study area. In some instances, field technicians encountered conditions within/along the canals that restricted access for surveying. In such instances, field technicians advanced within/along the canal wall to the extent practicable and assessed vegetation from a distance collecting photo documentation.
- During the evaluation of expanded recreational access to the canal system, Boott did not generate cost estimates to develop recreational access to the Lowell canal system, as proposed in the RSP. Boott did not develop these cost estimates because Boott does not have any rights to develop recreational access to the Lowell canal system.

8 Germane Consultation and Correspondence

A summary of germane correspondence and consultation related to the Recreation and Aesthetics Study is presented in Table 8-1. Appendix L provides copies of relevant correspondence.

Appendix A - Recreation Interview and Survey Forms

Personal Interview Survey Form

ON-SITE/IN-PERSON RECREATION INTERVIEW
Lowell Project (FERC No. 2790)
Recreation Survey

Boott Hydropower, LLC (Boott), a subsidiary of Enel Green Power North America, Inc., owns and operates the Lowell Project, which is licensed by the Federal Energy Regulatory Commission (FERC). The current operating license for the Project was issued on May 1, 1973 and expires on April 30, 2023. Boott will file its application with FERC for a new license for continued project operation no later than April 30, 2021. As part of this relicensing process, Boott is conducting a series of resource studies to enable FERC to prepare its environmental review document and develop a new operating license. The purpose of this survey is to gather information regarding participation in outdoor recreation activities at the Lowell Project.

Interview Location:			
Home Zip Code:	_____	**Date:**	_____
Age:	_____	**Time:**	_____
River Conditions:			_____
Are you:	**Male** ☐	**Female** ☐	**Prefer not to answer** ☐
Interviewer:			

Q-1. Regarding the Lowell Project area, do you consider yourself: (**Please circle one)**

1. A regular visitor to this area (*3 or more times per year*)
2. An occasional visitor (*1-2 times per year*)
3. An infrequent visitor (*Less than 1 time per year*)
4. This is my first visit

Q-2. On this trip to the Lowell Project area, when did you arrive?

Arrival Date **Arrival Time**

_____/_____/_____ _____AM/PM

When did you or do you expect to leave the Lowell Project area?

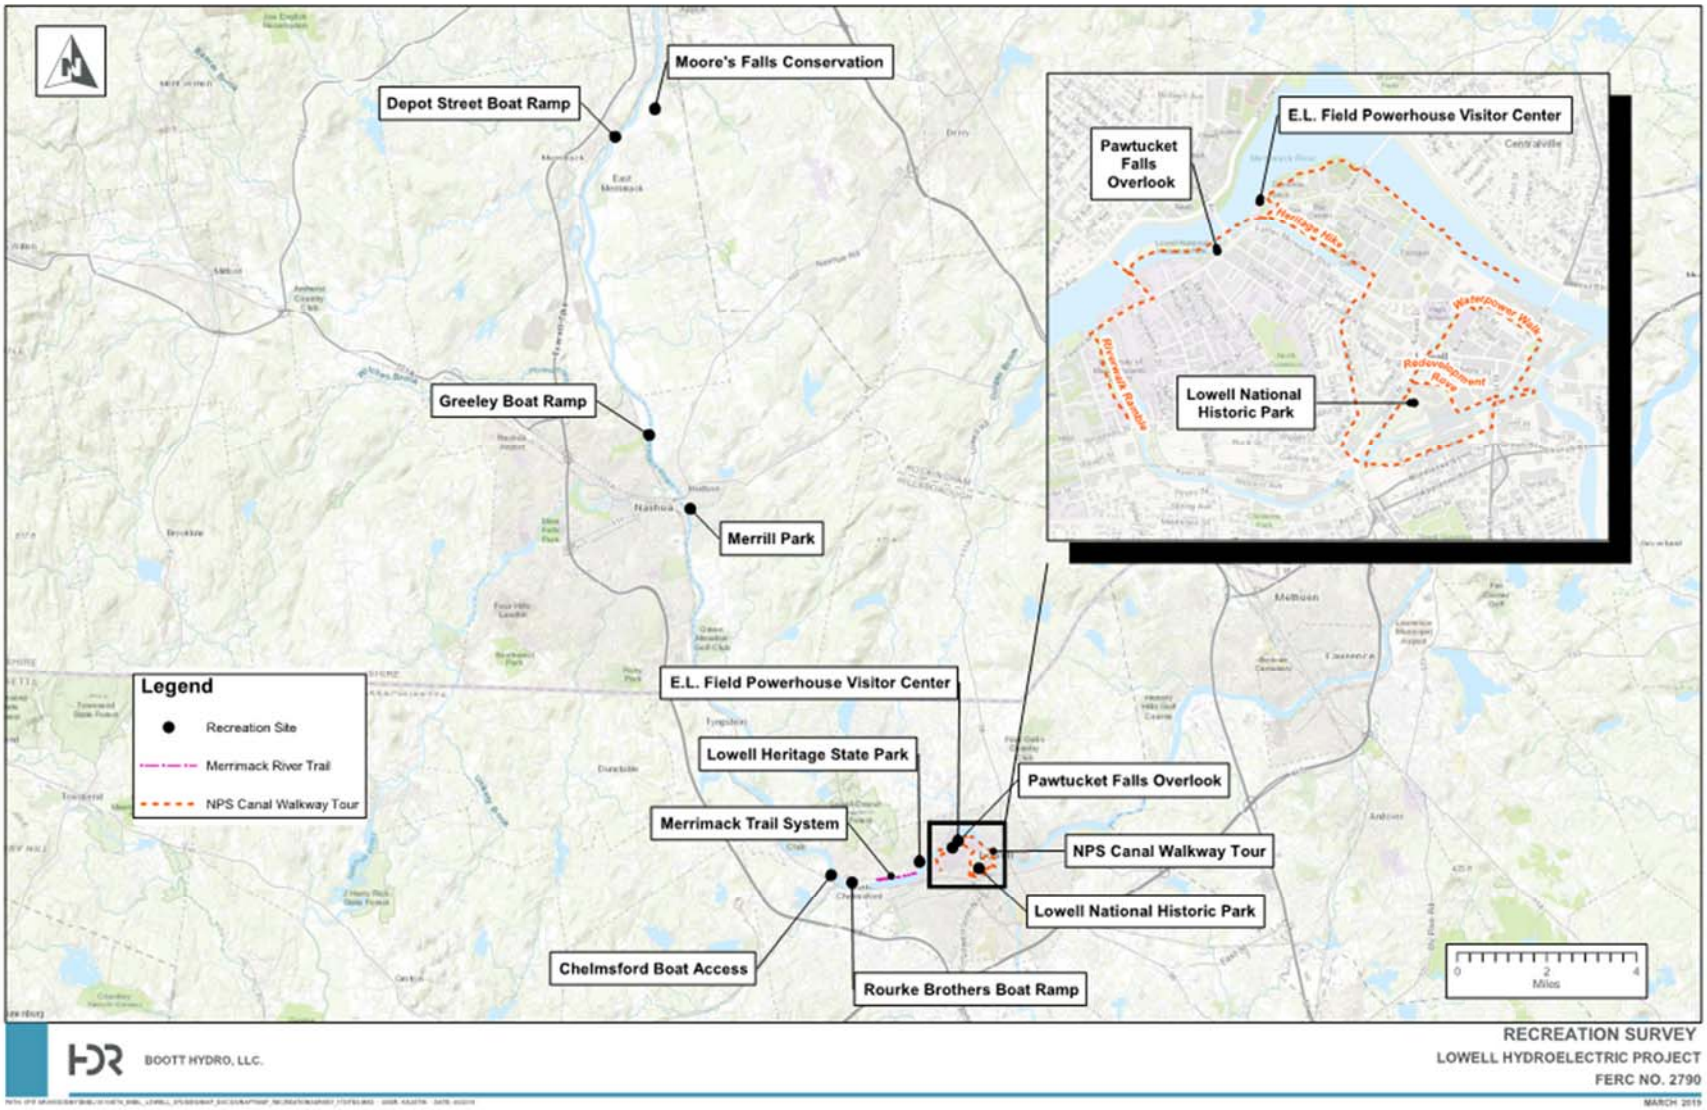
Departure Date **Departure Time**

_____/_____/_____ _____AM/PM

Q-3. During the last 12 months (including this trip), which month(s) did you visit the Lowell Project area?

A. _____

Project Area Recreation Map



Q-4. Which of the following recreation areas at or near the Lowell Project did you utilize for recreation during the past 12 months? **(Please circle all that apply)**

1. Lowell Heritage State Park
2. Merrimack River Trail
3. E.L. Field Powerhouse Visitor Center
4. NPS Walkway Tours
5. Riverwalk Ramble
6. Waterpower Walk
7. Heritage Hike
8. Northern Canal Walkway
9. Redevelopment Rove
10. Boat access facilities on the Project impoundment
11. Lowell Heritage State Park – Rourke Brothers Boat Ramp
12. Pawtucket Falls Overlook (Lowell, MA)
13. Chelmsford Boat Access (Chelmsford, MA)
14. Merrill Park (Hudson, NH)
15. Greeley Boat Ramp (Nashua, NH)
16. Depot St. Boat Ramp (Merrimack, NH)
17. Moore's Falls Conservation Area (Litchfield, NH)
18. Informal Shoreline Parking/Access Areas
19. None of the above
20. Other (Please list)

_____
_____
_____

Q-5. On your last trip, about how many miles did you travel to get to the Lowell Project?

A. _____miles

Q-6. Are you staying overnight in the Lowell Project area (not including at your own home) on this trip?

1. Yes 2. No

Q-7. If you answered yes to **Q-6**, at what type of accommodations will you be staying? (**Please circle one)**

1. RV/Auto/Tent Campground
2. Motel/hotel
3. Bed and Breakfast
4. Vacation or rental home
5. Other (Please specify: _____)

Q-8. How many people (including you) are in your group?

A. _____people

Q-9. Which of the following best describes your group during this trip?

1. Individual
2. Adult group (over 21)
3. Youth group (under 21)
4. Family (with children)
5. Mixed group (groups with children, adults, and/or teens)

Q-10. On this trip to the Lowell Project area, in which of the following activities have you or do you expect to participate? (**Please circle all that apply**)

1. Bank fishing	12. Canoeing	24. RV camping
2. Boat fishing	13. Kayaking	25. Tent camping
3. Guided fishing experience	14. Commercial whitewater boating	26. Photography
4. Walking tour	15. Museum-going	27. Sightseeing
5. Hiking	16. Shopping and/or dining	28. Relaxing
6. Backpacking	17. Swimming	29. Sunbathing
7. Guided canal tours	18. Off-highway vehicle (dirt bike/ATV)	30. Dog walking
8. Historical/heritage site visiting	19. Horseback riding	31. Painting/drawing
9. Running, jogging, and fitness	20. Off-road mountain biking	32. Other (please describe):
10. Rock climbing/bouldering	21. Road cycling	
11. Picnicking	22. Adventure sports	
	23. Geo-caching	

Q-11. Of the activities you circled in **Q-10** above, what is the primary activity that you participated in, or expect to participate in, on this visit? (**Please write in the corresponding number from above**)

A. Primary activity # _____

Q-12. Please rate the following for the primary activity you chose above:

	Totally Unacceptable	Unacceptable	Neutral	Acceptable	Totally Acceptable
Challenge	1	2	3	4	5

Safety	1	2	3	4	5
Enjoyment	1	2	3	4	5
River/Canal Flow	1	2	3	4	5
Crowding	1	2	3	4	5
Overall Experience	1	2	3	4	5

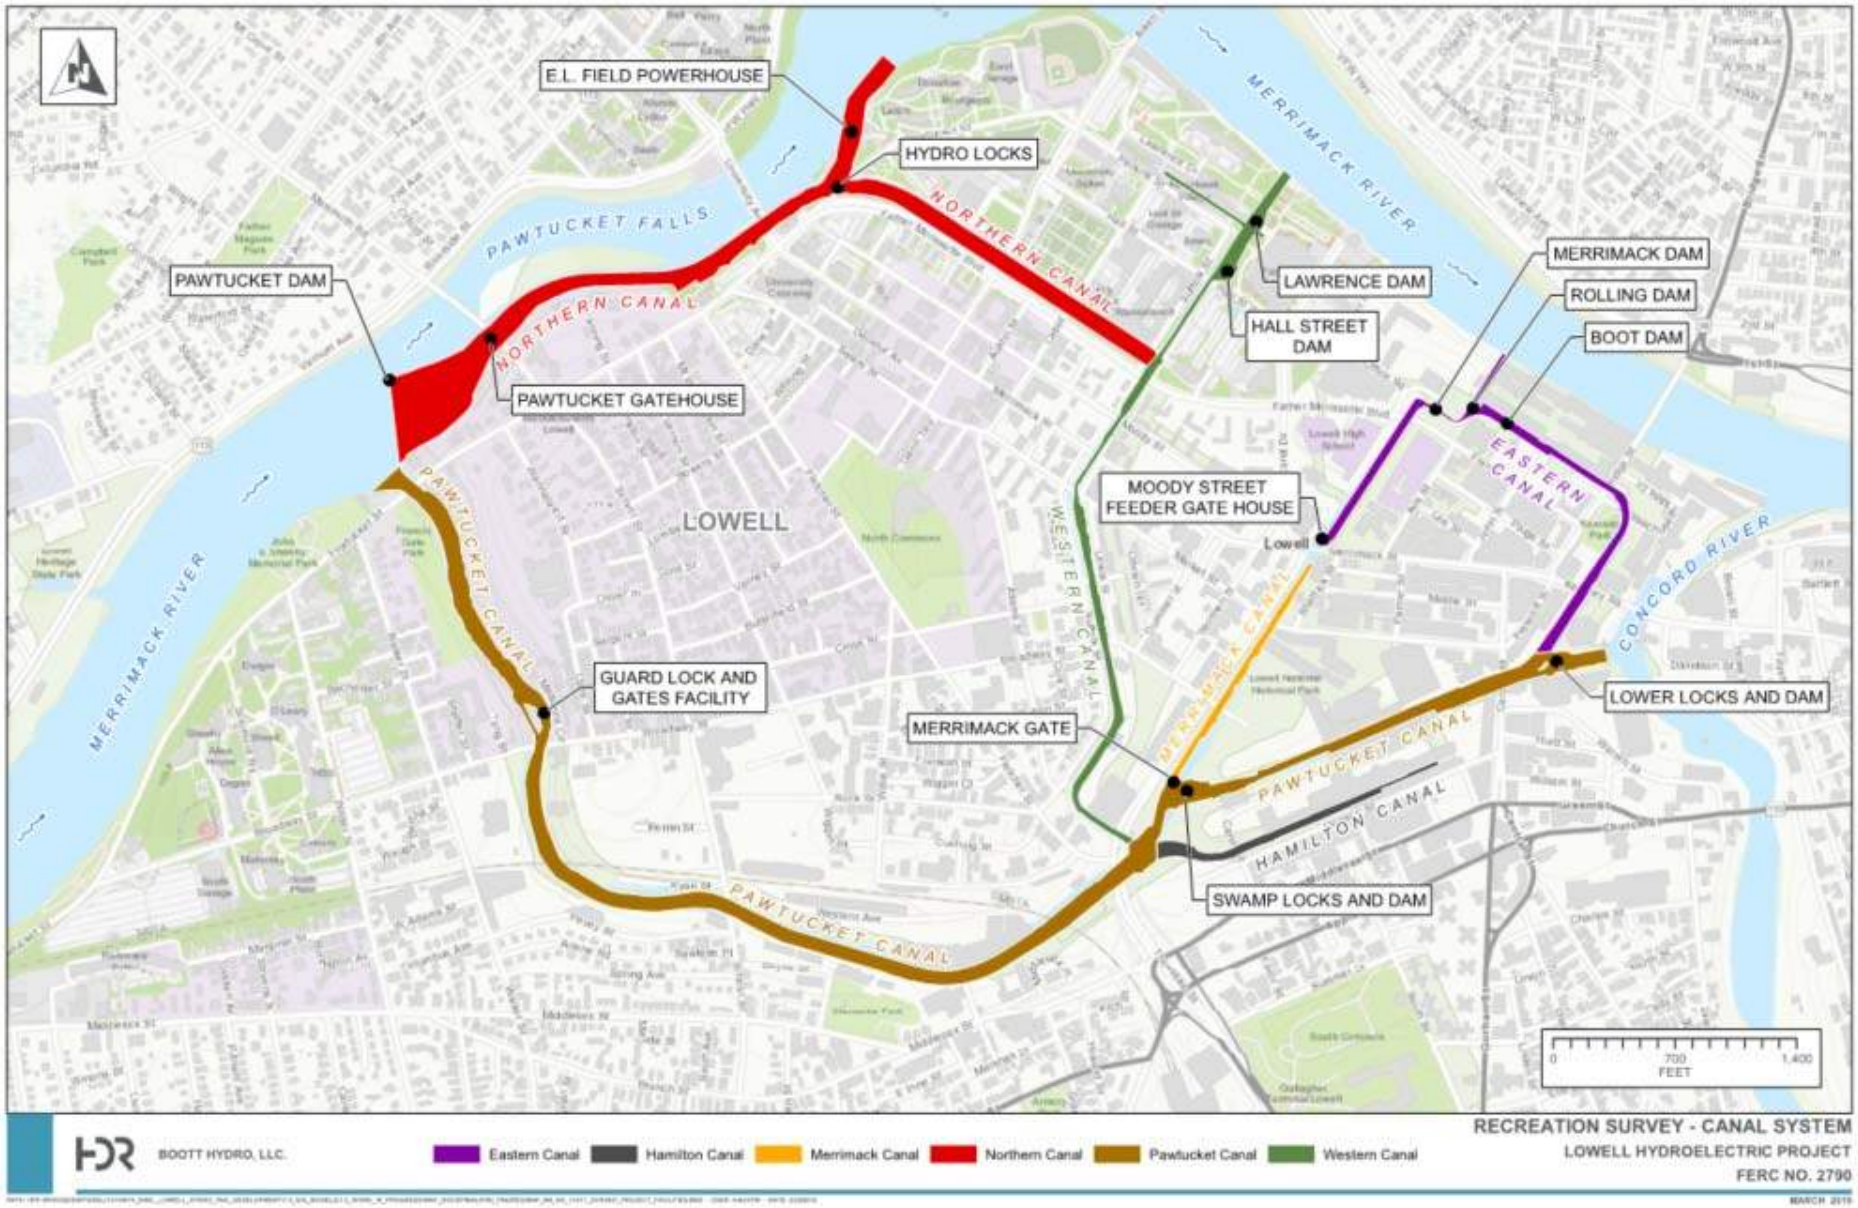
Q-13. Approximately how much money did you or do you intend to spend in preparation for or in association with your recreational trip to the Lowell Project (meals, gas, lodging, equipment, etc.)

A. $_____

Q-14. On previous visits to the Lowell Project, how would you rate the accumulation of waterborne trash in any of the canals shown in the figure below?

	Totally Unacceptable	**Unacceptable**	**Neutral**	**Acceptable**	**Totally Acceptable**
Eastern Canal	1	2	3	4	5
Hamilton Canal	1	2	3	4	5
Merrimack Canal	1	2	3	4	5
Northern Canal	1	2	3	4	5
Pawtucket Canal	1	2	3	4	5
Western Canal	1	2	3	4	5

Lowell Canal System



Q-15. On previous trips to the Project, please rate the following:

	Accessibility	Parking	Crowding	Condition of Recreation Facilities	Available Amenities	River/Canal Flow	Overall Experience
Lowell Heritage State Park							
Merrimack River Trail							
E.L. Field Powerhouse Visitor Center							
NPS Walkway Tours							
Riverwalk Ramble							
Waterpower Walk							
Heritage Hike							
Northern Canal Walkway							
Redevelopment Rove							
Boat access facilities							
Rourke Brothers Boat Ramp							
Pawtucket Falls Overlook							
Chelmsford Boat Access							
Merrill Park							
Greeley Boat Ramp							
Moore's Falls Conservation Area							
Informal Shoreline Parking/Access Areas							
Please use the following numerical scale to rate the formal recreation areas at the Lowell Project: 1) Totally Unacceptable; 2) Unacceptable; 3) Neutral; 4) Acceptable; 5) Totally Acceptable							

Q-16. Please tell us what type(s) of recreation enhancements you believe are needed and at what specific location(s) at the Lowell Project.

1. Type of recreation enhancement:_____

   Location(s):_____
   _____

2. Type of recreation enhancement:_____

   Location(s):_____
   _____

3. Type of recreation enhancement:_____

   Location(s):_____
   _____

Q-17. Please share any other comments that you have regarding recreation at the Lowell Project:_____
_____
_____
_____
_____
_____
_____
_____
_____

Thank you for completing the Recreation Survey!

Online Recreation Survey Form

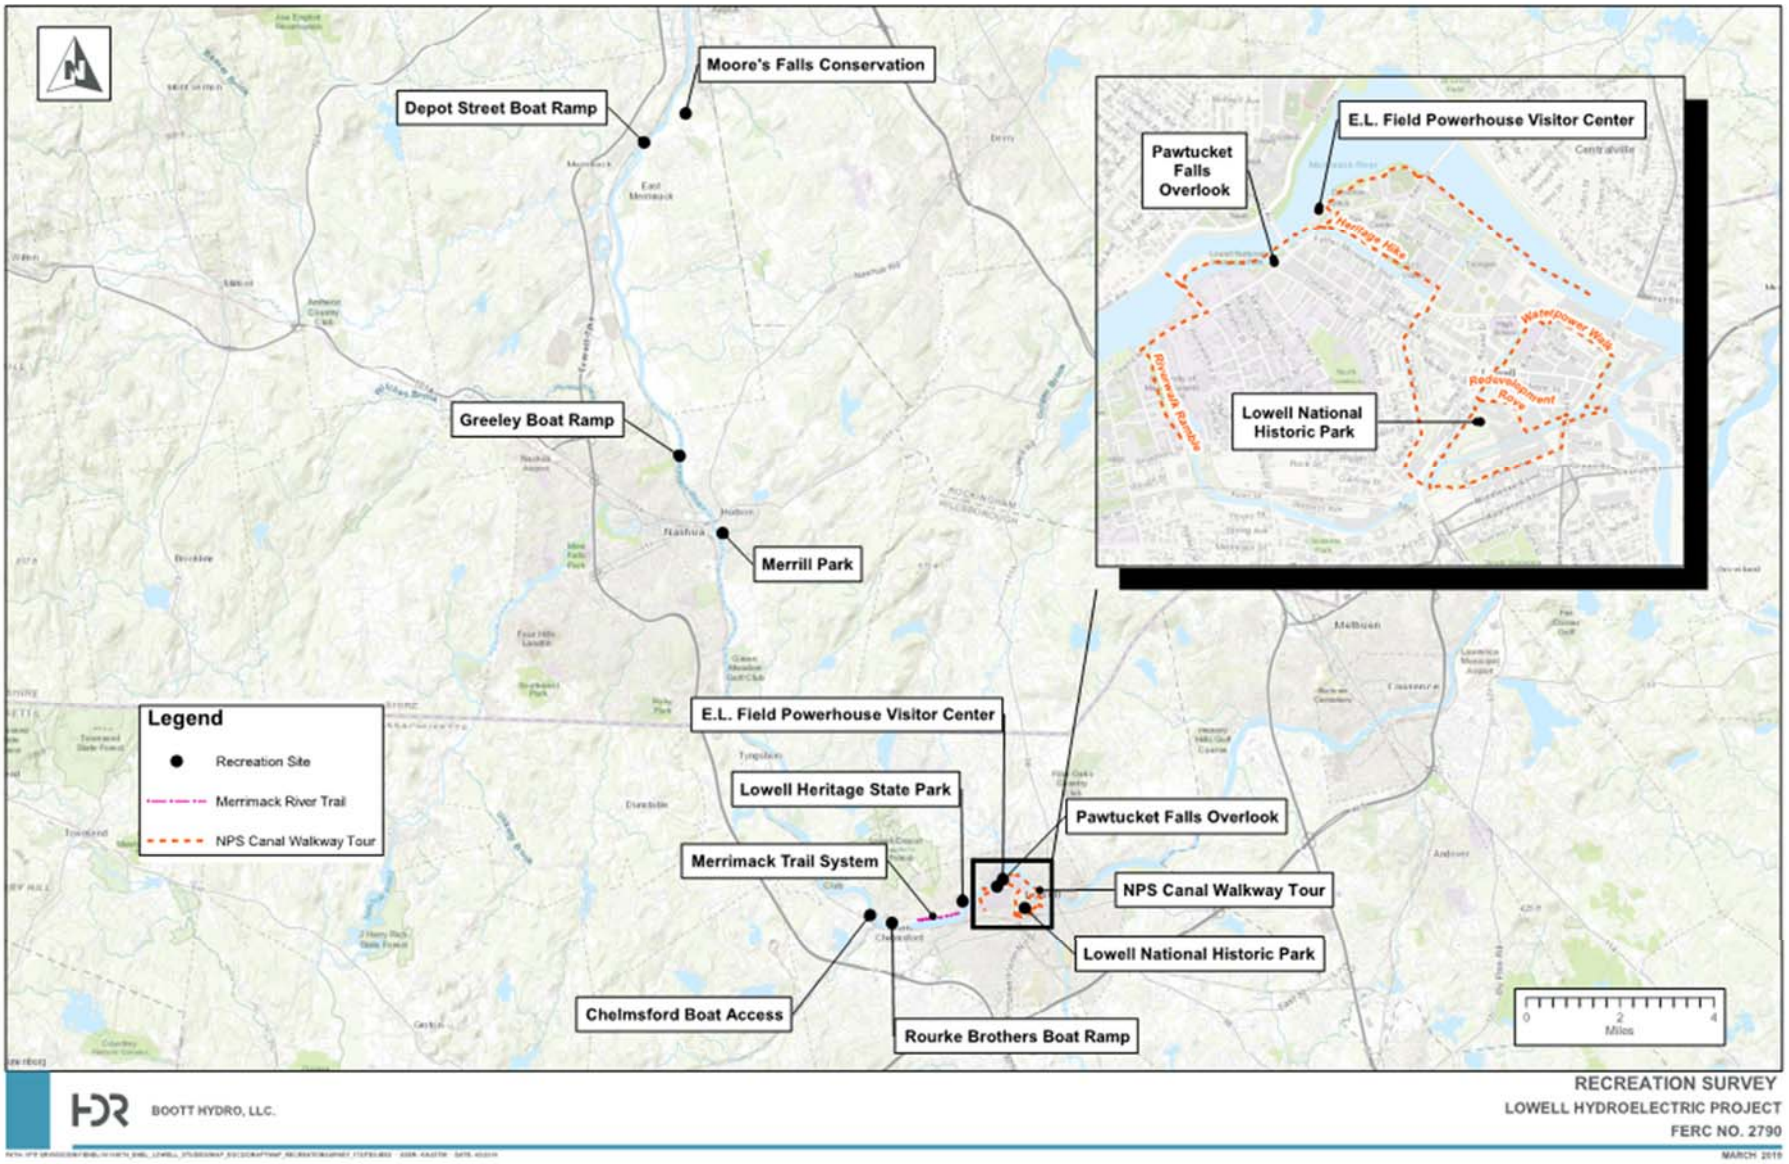
Boott Hydropower, LLC (Boott), a subsidiary of Enel Green Power North America, Inc., owns and operates the Lowell Project, which is licensed by the Federal Energy Regulatory Commission (FERC). The current operating license for the Lowell Project was issued on May 1, 1973 and expires on April 30, 2023. Boott will file its application with FERC for a new license for continued project operation no later than April 30, 2021. As part of this relicensing process, Boott is conducting a series of resource studies to enable FERC to prepare its environmental review document and develop a new operating license.

The purpose of this survey is to gather information regarding participation in outdoor recreation activities at the Lowell Project.

The E.L. Field Powerhouse Visitor Center is the Lowell Project's only formal recreation area. Other, non-Project recreation facilities are also located near the Lowell Project, including the Lowell National Historical Park, Merrimack River Trail, Pawtucket Falls Overlook, boat access facilities on the Lowell Project impoundment, and the Rourke Brothers Boat Ramp. These and other non-Project facilities are not owned or operated by Boott, but are popular Merrimack River recreational areas. In addition, there are numerous informal access areas on Lowell Project lands that are used by the public to access the Merrimack River.

The Lowell Project area relevant to this survey is defined on the map. The information provided in this survey will inform the development of appropriate management measures for recreational resources at the Lowell Project.

Lowell Project Area Recreation Map



Q-1. What is the zip code of your primary residence? _____

Q-2. What is your age? _____

Q-3. Are you: Male ☐ Female ☐ Prefer not to answer ☐

Q-4. Regarding the Lowell Project area, do you consider yourself:

5. A regular visitor to this area (*3 or more times per year*)
6. An occasional visitor (*1-2 times per year*)
7. An infrequent visitor (*Less than 1 time per year*)

Q-5. During the last 12 months, which month(s) did you visit the Lowell Project area? *(select all that apply)*?

Jan ☐ Feb ☐ Mar ☐ Apr ☐ May ☐ Jun ☐ Jul ☐ Aug ☐ Sep ☐ Oct ☐ Nov ☐ Dec ☐

I have not visited in the last 12 months ☐

Q-6. Which of the following recreation areas at or near the Lowell Project did you utilize for recreation during the past 12 months? **(Please select all that apply)**

21. Lowell Heritage State Park
22. Merrimack River Trail
23. E.L. Field Powerhouse Visitor Center
24. NPS Walkway Tours
25. Riverwalk Ramble
26. Waterpower Walk
27. Heritage Hike
28. Northern Canal Walkway
29. Redevelopment Rove
30. Boat access facilities on the Lowell Project impoundment
31. Lowell Heritage State Park – Rourke Brothers Boat Ramp
32. Pawtucket Falls Overlook (Lowell, MA)
33. Chelmsford Boat Access (Chelmsford, MA)
34. Merrill Park (Hudson, NH)
35. Greeley Boat Ramp (Nashua, NH)
36. Depot St. Boat Ramp (Merrimack, NH)
37. Moore's Falls Conservation Area (Litchfield, NH)
38. Informal Shoreline Parking/Access Areas
39. None of the above
40. Other (Please list)

_____
_____
_____

Q-7. On your last trip, about how many miles did you travel to get to the Lowell Project?

A. _____miles

Q-8. During the past 12 months, when did you visit the Lowell Project? **(Please select one)**

1. Only on weekdays (Monday – Friday)
2. Only on weekends (Saturday or Sunday) and/or holidays
3. Both weekdays AND weekends and/or holidays

Q-9. On previous visits to the Lowell Project have you stayed overnight (not including your own home)?

2. Yes 2. No

Q-10. At what type of accommodations do you usually stay? (**Please select one)**

6. RV/Auto/Tent Campground
7. Motel/hotel
8. Bed and Breakfast
9. Vacation or Rental Home
10. Other (Please specify: _____)

Q-11. What was the approximate size of your group during your last trip to the Lowell Project area?

A. _____people

Q-12. Which of the following best describes your group during previous trips to the Lowell Project Area?

6. Individual
7. Adult group (over 21)
8. Youth group (under 21)
9. Family (with children)
10. Mixed group (groups with children, adults, and/or teens)

Q-13. On previous trips to the Lowell Project area, in which of the following activities have you or do you expect to participate? (**Please select all that apply**)

1. Bank fishing	12. Canoeing	24. RV camping
2. Boat fishing	13. Kayaking	25. Tent camping
3. Guided fishing experience	14. Commercial whitewater boating	26. Photography
4. Walking tour	15. Museum-going	27. Sightseeing
5. Hiking	16. Shopping and/or dining	28. Relaxing
6. Backpacking	17. Swimming	29. Sunbathing
7. Guided canal tours	18. Off-highway vehicle (dirt bike/ATV)	30. Dog walking
8. Historical/heritage site visits	19. Horseback riding	31. Painting/drawing
9. Running, jogging, and fitness	20. Off-road mountain biking	32. Other (please describe):

10. Rock climbing/bouldering	21. Road cycling
11. Picnicking	22. Adventure sports
	23. Geo-caching

Q-14. Of the activities you circled in **Q-13** above, what is the primary activity that you participated in during previous visits? (**Please write in the corresponding number from above**)

A. Primary activity # _____

Q-15. You selected (Primary Activity Number) as the Primary activity in Question 14. Please rate the following:

	Totally Unacceptable	Unacceptable	Neutral	Acceptable	Totally Acceptable
Challenge	1	2	3	4	5
Safety	1	2	3	4	5
Enjoyment	1	2	3	4	5
River/Canal Flow	1	2	3	4	5
